

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

## TO THE KING.

---

SIRE,

It is now upwards of seventeen years since Your Majesty did me the honour to appoint me Your Gardener at Kensington and St. James's; during which time I have made a great variety of experiments on Fruit and Forest Trees, and introduced the mode of Pruning and Training recommended in the following Treatise.

A 2

M366895

Your Majesty has, at different times, graciously condescended to examine the process, and been pleased to express Your approbation of the Improvements in such favourable terms, as to cause my heart to overflow with unspeakable pleasure.

Such encouragement from my Royal Master has stimulated me to proceed with so much alacrity and perseverance, as to overcome every difficulty that opposed me, and to bring the subjects treated of in this Volume to such a state of perfection as will, I flatter myself, in some measure render it worthy of Your Majesty's patronage.

Permit me then, Sire, with the most profound humility to lay this Work at Your Majesty's feet ; and thus publicly to acknow-

( v )

ledge my gratitude to the best of Sovereigns,  
and the best of Masters, for the innumerable  
blessings which under him I enjoy, both as a  
Subject and a Servant.

That Your Majesty may long live to pa-  
tronize the Arts and Sciences, and to reign  
over a loyal, brave, and happy people, is the  
daily prayer of,

Your Majesty's

Most grateful and most devoted

Humble Servant,

**WILLIAM FORSYTH.**

pleasure affirm, that the quantity of fruit has been remarkably increased, and the quality greatly improved.

I have in the following pages stated many facts, to evince the utility of the Composition recommended, and to induce others to make a fair trial, which may be done at a very trifling expence.

I only request of those who entertain any doubts, that they will make choice of two trees of the same kind, as near as may be in the same state of health or decay, and having equal advantages of soil and situation ; let the dead, decayed, and injured parts be cut out ; then to one of the trees apply the Composition as directed in this Treatise, and leave the other to Nature : if proper attention be paid to the former, no great length of time will be necessary to show which method ought to be pursued in future.

I hope the candid reader will pardon me for dwelling a little on this subject. It has been said, that there is nothing new either in the Composition or its application. It is certainly true, that Compositions of various kinds have been tried : but no one has been attended with such great success as that which is described in the following pages ; indeed, they were generally made up in a slovenly manner, and applied without properly preparing the trees, so that little good can have been expected, even if the Composition had consisted of proper materials. In these particulars I am persuaded, that every impartial person will acknow-

ledge, that I have made great improvement. Former Compositions have been made up of loam and cow or horse-dung, of bees-wax, pitch, tar, chalk, rosin mixed with grease, gums, &c. It is granted, that such as these may sometimes be of use, but not in general; most of them being liable to become hard, and to crack and peel off. I have tried them all, with but very little success. I have also tried a Composition of tarras (which is used as a cement for building under water): this also cracked and peeled off after it became hard. Some of these compositions become so hard, that, instead of giving way to the new bark as it is produced, they cut and tear it, to the great injury of the tree.

The Composition which I recommend is not liable to these inconveniencies; it possesses an absorbent and adhesive quality, and is moreover of such a nature as not in the least to hurt the new and tender bark; for it easily gives way to it, and to the new wood, as they advance. On applying it to trees which contain a strong acid, such as Oaks, Apple trees, Apricots, &c. when infected with the canker, that disease may be seen oozing through the Composition and adhering to the outside, like copper-dust, or rust of iron, and may be easily rubbed off with the hand. This appearance I never could observe on the application of any other Composition; which confirms my belief that it acts as a strong stimulant.

When the wounds in fruit trees are so large as not to heal up in the course of a twelve-month, I

renew the Composition annually, which, on its application, invigorates the trees, and seems to have the same effect on them as a top-dressing of dung has on land.

I have been solicited by some of my friends to add a chapter on forcing Grapes, Peaches, and Nectarines; and to give a description of a house for that purpose; but as it would swell the book to too great a size, and as the subject is fully treated of by many others, it seems unnecessary to say any thing farther here, than just to observe, that the method of pruning and training recommended in this book is equally applicable to trees in a forcing-houses as to those on a natural wall. When Vines are trained straight up the rafters of hot-houses, they throw out a few eyes only at top, and all the rest of the branch becomes naked; but when trained in a serpentine manner, they break equally.

Dwarf Peaches and Nectarines planted in the pits of forcing-houses should be trained horizontally; in which mode they will produce much more fruit than when they are trained fan-fashion.

It must be observed, that the Directions, &c. in the following pages are calculated for the neighbourhood of London; it will, therefore, be necessary to make allowance, in other climates, for the earliness or lateness of their seasons, both with regard to the time of fruit being in perfection, and also for planting, pruning, &c.

For the information of those who are not acquainted with practical gardening, the following explanation of what is called *heading down* is given.

When young trees are planted out from the nursery, as soon as they begin to break in the Spring, they are cut down to three or four eyes, according to their strength, to furnish them with bearing wood: if this were not done, they would run up in long naked branches, and would not produce one quarter of the fruit which they do when this operation is properly performed. The same holds good in heading all kinds of old trees.

An opinion prevails, particularly in those parts where Apple trees are cultivated to any considerable extent, that trees never bear well after heading down, and that it frequently kills them. This may, no doubt, happen when they are improperly headed down all at once, by giving a sudden check to the sap, the few weak shoots not having strength to draw up what is supplied by the roots; and moreover not being capable of sheltering one another, they are chilled by the cold, and so rendered, at least, unproductive, if they are not totally killed. But if heading were done gradually, that is, if every other branch all over the tree were headed at a proper length, cutting as near to those parts where the shoots appear as possible, in the month of February or March, or even as late as May, in the course of the Summer they would throw out fine long shoots. These should not be shortened the first year unless it be necessary to shorten a few to fill up the head of the tree with bearing wood, and that should be done in the following Spring; cutting them to six or eight inches long, according to their strength.

In the next Spring after the first branches are headed, the remaining old branches may be cut out; and these will soon fill the head of the tree with fine bearing wood. In three years, if properly managed, trees so headed will produce a much greater quantity of fruit, and of a better quality than they did before the operation was performed.

# PREFACE

TO

THE SECOND EDITION.

---

WHEN the first Edition of this work appeared in print, it became certainly at once a candidate for public favour, and an object of professional criticism. Its reception in the former character has been to me honourable and gratifying in the extreme\*; and had Criticism exercised its talent with personal candour and liberality, its remarks on points of practice or hypothesis should have met with respect and attention from me; even though they had shown my positions to be erroneous; but its utmost severity would not have extorted a word of *complaint*. Nor shall I now trespass longer on the time or patience of the

\* An impression of 1500 copies, in 4to., having been sold in little more than eight months.

Reader, than briefly to reply to a few points, which tend to affect, not so much my professional reputation, as my personal character.

Thomas Andrew Knight, Esq. in a pamphlet lately published \*, tells his readers that he has “*suspected a Combination* between Dr. Anderson and Mr. Forsyth.” To be *suspicious*, is certainly not a quality that easily enters into the composition of a cultivated and an honourable mind ; nor ought the serious charge of COMBINATION to be lightly made against men of fair repute.

“ I believe,” says Mr. Knight to Dr. Anderson, “ that you are actuated [that is, in having recommended Mr. Forsyth’s Experiments at Kensington] by some motive of *private interest*, with which the Public are not acquainted [but which, it seems, Mr. Knight was determined should be no longer a secret]. Is Dr. Anderson quite sure, that he is not the concealed Writer, either wholly or in part, of his friend Mr. Forsyth’s book, and the intended *sharer of his Profits*? And has not Dr. Anderson taken out a patent for a new kind of forcing-house, *whose* excellence his disinterested friend Mr. Forsyth *stands forward* to attest?”

Now considering that no part of the foregoing

\* Intituled, “ Some Doubts relative to the Efficacy of Mr. Forsyth’s Plaster in filling up the Holes in Trees, &c. ascribed to it by Dr. Anderson and Mr. Forsyth : In a Letter to Dr. Anderson.”

paragraph has any other foundation than in the creative fancy of Mr. Knight, the language in which it is conveyed does not appear to be quite so temperate, or so qualified, as might be expected from one Gentleman in addressing another.

Dr. Anderson sees, no doubt, in what manner it is proper for him to treat an insinuation so illiberally made.\*

\* The Doctor has since publicly invited Mr. Knight to an amicable arbitration, in the following manly terms ;

“ To T. A. Knight, Esq.

“ SIR,

“ When I was first told that you had published a Letter addressed to me, on the subject of Mr. Forsyth's Treatment of Trees, I felt no anxiety concerning it, nor was at any pains to procure the book. I conceived that it was written by a Gentleman, and that of course it could contain nothing that was unbecoming one of that character to write ; and, as what we had both said on that subject was before the Public, I felt no difficulty in abiding the decision of that Public concerning it. I am sorry, however, to find, on reading your book of late, that I had been in a mistake concerning you ; and that you had there published such things as necessarily call upon me to take this public notice of them. It would be degrading to the character I bear, however, to multiply assertions unsupported by proofs, which might be contradicted in the same manner as I have experienced, without affording to the Public any adequate means of discriminating truth from falsehood. In order to avoid this futile kind of altercation, and to elucidate the truth at once, without danger of error, I beg leave to

For *myself* it remains only to pledge, as I hereby do, my character as a Man graciously honoured in being the servant of His Majesty — that the above suspicions and insinuations are absolutely unfounded ; — that Dr. Anderson not only did not write one line of my book, but never saw my work till the MS. (composed entirely by myself) was in a complete state of preparation for the press, nor even read a page of it in that state ; — that the Doctor never was chargeable with such absurdity, as to expect or desire to share in the profits of a Publication, of which he had neither designed nor executed the smallest part ; — and, that, so far from my having distinguished myself

---

propose, that when you next come to London (which I understand you usually do once a year,) you will be so candid as to appoint a day and hour when you will meet with me in Kensington Gardens, accompanied by some Gentlemen of sound understanding, who are capable of observing facts, and of drawing just conclusions from them ; and if I shall then fail in proving to their full conviction, from undeniable evidence to be then produced, that you have published in that work unfounded and injurious calumnies, and that you have represented things in a manner very different from what, on a thorough examination, they will be found to be, I shall submit to any punishment that these Gentlemen shall please to award, on the supposition that you previously agree to submit to their award, should the case be reversed. This is the only answer that your book seems to claim from,

“ JAS. ANDERSON.

“ *Isleworth, December 20. 1802.*”

on the subject of Dr. Anderson's Patent for a forcing-house, the Doctor well knows, that motives of delicacy, more creditable to myself, perhaps, than pleasing or candid towards him, made me resolutely decline to do what, in any other circumstances, would have been but a common act of justice and friendship. As to my having *stood forward to attest, &c.* I really know not in what part of my book, or where else, Mr. Knight can find that I have so done.

As to Mr. Knight's account of his Visit to Kensington Gardens, and his opinions of the Trees under experiment there (evidently viewed by him with an eye of prejudice), I shall contentedly leave them to operate as they may: not apprehending that I assume too much, when I say, that in my humble opinion, a person who (for an insidious purpose) can "*affect total ignorance*" [these are his own words] on a subject which he at the same time *professes fully to understand*, has little claim to notice either in answer or explanation.\*

\* Mr. Knight's remark, of its being "more certain that I was paid for an important discovery, than that I made one," is, perhaps, more entitled to praise for its ingenuity, than for its civility towards the Noble Peers and Honourable Members of Parliament on whose examination and report to His Majesty the reward was ordered to be granted (see p. 448. of this volume); and who were selected, as being the most competent

As to the fact mentioned by him, of my having pointed out a branch as being of three years' growth, which he perceived to be of five; those who know any thing of the subject are aware, that the annual growth of timber is so regularly and so obviously marked by Nature, that I must have been stark mad to have attempted so futile an imposition on any person who had the blessing of eye-sight.

In one part of his pamphlet, Mr. Knight has the following observation :

“ That Mr. Forsyth may have trained up a young Shoot from the bottom of an old Tree that was partially hollow, and that such a shoot may

---

judges of the subject that could be named in the kingdom ; — if I may so say without offence to the judgment and experience of Mr. Knight.

His insinuation, however, p. 13, “ that I have supplied my Royal Master's table, by procuring fruits from Covent Garden Market, and sending them as the produce of Kensington,” I despise for its malignity, and yet must smile at for its absurdity. Not an article of fruit is ever sent to His Majesty's table that has not been previously entered in a book kept for that purpose; and the simple fact, that I must myself have borne the entire expence of such supposed purchases from Covent Garden, or any other market, will not be thought a very strong circumstance in favour of the practice. The truth is, that I have never once, during my servitude at Kensington, made, or had an idea of making, such a purchase as Mr. K. alludes to.

have made a good tree, is nothing wonderful; for the roots of almost all our grafted trees show no disposition to perish with the graft or bud, which they nourish; and a shoot thus trained would certainly make, as I have often observed, as good a tree as any other of the same variety. — But some trees do not readily emit young shoots of this kind; and I should like much to know how many Peach or Nectarine Trees died under Mr. Forsyth's process of rendering them immortal."

I consider myself much indebted to Mr. Knight for the very handsome compliment that he has here (unintentionally, it is true,) paid to my practice. Could I be vain of any such thing, I should certainly be so of this; particularly as it comes from one who will not easily be suspected of any intention to flatter. It also places my Composition in a much more conspicuous light than that in which I should otherwise, perhaps, have regarded it. I shall therefore answer him with pleasure. From the manner in which the question is put, it should seem, Mr. Knight thinks that the operation of cutting over a decayed *Peach-tree* is of so dangerous a nature, as to render it impossible to prevent a large proportion of such trees as have been cut over from dying. A great majority of those Gardeners who have tried it, by *the common mode of practice*, will perhaps coincide with him in this

opinion. But I can with satisfaction assure him, that from the time when I first applied my plaster to such wounded trees, which is now many years since, it escapes my recollection, and that of many others who have been constantly employed in the Royal Gardens at Kensington, that a *single tree*, either Apricot, Peach, or Nectarine, has died from being cut over, while *under my mode of management*; though that operation has on some occasions been performed under circumstances extremely unfavourable to its success; in particular, four trees, namely, three Peach and one Nectarine; which had been dug out of the ground and laid on a mouldy heap, exposed to the rigour of severe frosts, &c. Those trees are now open to the view of Mr. Knight, or any other gentleman who may choose to inspect them. I find, however, that it is not a few only of such trees that have been headed-in by me; for, upon an investigation with a view to answer this question, I numbered no fewer than sixty Peach, Apricot, and Nectarine Trees, that have been so cut over and restored to a high state of health and fruitfulness, and which are now in as flourishing a state as I could wish trees of that sort to be. Neither were these operations performed in secret, or with any view to concealment, but openly, under the eye and with the assistance of the Gardeners employed in the gardens, who have all had opportunities to

observe the progress of experiments. As to the idea of Mr. Knight, that if such decayed trees have actually put forth new shoots at all, it must have been from the roots only, and from no other part; the short answer to this is, that he is under a great error; for every Gardener knows, that if this had been the case, the trees must all have been budded anew before they had come into bearing: Now the fact is, that none of those trees have ever been budded again.

So far is the operation of budding in this instance unnecessary, that I have been obliged to cut over some old trees, particularly one kind of Cherry (of the Heart species), in order to preserve the kind that they bore, which could be obtained no where else, and which were past bearing in their old state; but they have now plenty of young wood, and are in full bearing. I have, therefore, most certainly to thank Mr. Knight for having induced me to bring forward these strong facts before the public; which, but for him, I never should have thought of doing.

From the same consideration, I shall look forward with pleasure to the prospect of having other facts of a similar nature investigated upon the spot, by gentlemen who will not be suspected of partiality to me, under the watchful care and guidance of Mr. Knight, at a meeting proposed by Dr. Anderson; and which I hope nothing will

prevent from taking place. The more minute the investigation may be, it will in the result, as in the above instance, be the more satisfactory to me.

I think it but respectful to my Readers, and a justice to myself, to declare, that the *Contents of the following Work are solely the result of my own practice and experiment*\*; every single remark having been minuted down at the moment of its occurring, and only retained afterwards on my ascertaining, by due proof, that it was well founded and accurate. Of books I have never availed myself, farther than as they might tend to assist in perfecting my Catalogues of Fruits; for at a time when I did once begin to read with a view to the improvement of my practice, I soon found myself more bewildered than instructed, and have never since resumed the task.

To conclude: After acknowledging with the deepest sensations of gratitude, the candour and kindness of a generous Public, I shall, from this moment, cease to notice any similar attacks from Mr. Knight, or any other quarter: contenting myself with opposing, to the ungenerous, unjust, and unprovoked charges of an individual, a few only of the *voluntary* testimonies of Gentlemen of dis-

\* With the exception only of some remarks on the common mode of grafting, which I have avowedly taken from Miller, for the purpose of showing how it is improved.

tinguished honour and indubitable veracity, with which I have been favoured. \*

\* See Letters from Dr. Guthrie, Mr. Martin, Mr. Wedgewood, and Mr. Davies, p. 472 to 480: testimonies which could it be thought necessary, I might corroborate by the insertion of at least fifty others, from gentlemen of the first practical knowledge in the kingdom: the more flattering, as most of the writers were entire strangers to me.

## POSTSCRIPT

TO

*THE THIRD EDITION.*

---

SINCE the printing of this Third Edition was completed, I have been fortunate enough to have derived an accession of most respectable testimonials, tending to remove any doubts that may have arisen in the public mind respecting the verity of my statements on the subject of my Composition.

The visit which I had the honour to receive from the undersigned gentlemen was wholly unexpected on my part; originating, as I am given to understand, solely from a conversation among themselves, and a desire on the part of some of the company to remove the doubts of the others.

*“ To Mr. Forsyth, Royal Gardens, Kensington.*

“ SIR,

“ As you had the goodness lately to give us an opportunity of examining several trees in Kensington Gardens, in the various stages of renovation, or filling-up with new wood; and as reports have been circulated, tending to discredit

the efficacy of your process; — We feel it an act of justice, not only to you, but to the Country, which is deeply interested in your discoveries, thus publicly to declare, that the statements you have published on the subject contain nothing more than the truth.

**TREATISE**

ON THE

**CULTURE AND MANAGEMENT**

OF

**FRUIT TREES, &c.**

---

**CHAPTER I.**

**OF APRICOTS.\***

*Different Sorts described. — Planting and Heading. — The Management of decayed Trees. — Pruning of Apricots, and how to shelter them from Cold.*

**THE** Apricot, we are told, came originally from Armenia, whence it takes the name of Armeniaca, and was cultivated in this country in 1548. *Turner's Names of Herbes, sign. Juij.*

\* We shall enumerate, under their respective heads, the principal sorts of fruit that are propagated in this country; with the time of their ripening, as near as possible. It is to be observed, however, that the diversity of seasons, together with that of soil and situation, will sometimes make a month of difference in the ripening of the fruit.

Linnæus, according to the Sexual System, arranges it in the twelfth class, Icosandria Monogynia \* ; and comprehends in the genus *Prunus*, the Apricot, the Cherry, the Bird-Cherry, &c. ; making them only different species of the same genus. The Apricot is named *Prunus Armeniaca*.

Although the above-mentioned plants are arranged under the same genus, yet the Cherry and Plum will never take upon each other, nor the Apricot upon the Cherry ; but the Apricot will take upon all sorts of Plums except the Brussels.

*The Names and Qualities of Apricots commonly cultivated in England, with the Time of their Ripening.*

1. MASCULINE. *Duham. n. 1. tab. 1. Pom. Franc. 1. p. 29. t. 2. f. 1. Pom. Aust. t. 51.* This is a small roundish fruit. It is the earliest of all the Apricots, ripening about the latter end of July ; and is chiefly esteemed for its tart taste. When fully ripe, it is of a red colour towards the sun, and of a greenish yellow on the other side.

2. ORANGE. This is pretty large, but rather dry and insipid, and fitter for tarts than for the table. It is of a deep yellow colour, marked with red next the sun when ripe, which is about the latter end of August. This is considered as the best for preserving.

\* Most of our eatable fruits are arranged under this class ; and it is remarkable, that there is not one poisonous fruit to be found in it.

3. **ALGIER.** This is a flatted oval-shaped fruit, of a straw colour, juicy, and high-flavoured. It ripens about the middle of August.

4. **ROMAN.** *Langley Pom. tab. 15. f. 4.* This fruit is large, almost round, of a deep yellow colour, the flesh firm and juicy. It is ripe about the middle or latter end of August.

5. **TURKEY.** *Langley Pom. tab. 15. f. 2.* This is very large, oval, compressed at the sides, and of a deep yellow colour; the flesh is firm, and of a good flavour. It ripens about the latter end of August.

6. **BREDA.** (Brought thence to England.) This is originally from Africa. It is large, round, and of a deep yellow colour; the flesh is deep yellow, soft and juicy. This is an excellent fruit, especially if ripened on a standard. It ripens about the latter end of August.

7. **BRUSSELS.** *Pom. Aust. tab. 57.* This is held in very great esteem on account of its bearing so well on standards, or large dwarfs. It is of a middling size; red towards the sun, with many dark spots; and of a greenish yellow on the other side. This has a brisk flavour, is not liable to be mealy or doughy, and is preferred by many to the Breda; but when the Breda is planted as a standard, the fruit is more juicy and of a richer flavour. This ripens in August on a wall, but not before the latter end of September on standards.

8. **MOOR-PARK.** *Hooker Pom. Lond. tab. 9.* This is called also Anson's, Temple's, and Dun-

more's Breda. It is a fine large-sized fruit, of a bright gold or orange colour, with dark spots; but the side next the wall is often greenish and hard: the flesh is also bright orange, juicy, and excellent. It ripens about the latter end of August.

9. PEACH APRICOT; *Apricot of Nancy. Duham. n. 10. t. 6. Pom. Franc. 1. p. 37. t. 7. f. 10. Pom. Aust. tab. 59.* This was introduced from Paris, by his Grace the Duke of Northumberland, at Sion-house, in 1767. It is the finest and largest of all Apricots, and is generally thought to be the same as the Moor-Park; but upon a minute examination the leaves will be found to differ. It ripens in August.

10. BLACK APRICOT. *Pom. Franc. 1. p. 36. t. 6. f. 9. Pom. Aust. tab. 60. Poit. et Turp. Fr. tab. 19.* This has been very lately introduced, by Sir Joseph Banks, from France, in which country it is highly esteemed.

The trees that Sir Joseph planted in his gardens at Spring Grove, near Hounslow, bore fruit last season, for the first time in this country; but in consequence of the wet and unfavourable weather, it did not arrive at perfection.\* It ripens about the second week in August.

\* Since writing the above, I have had the honour of paying Sir Joseph a visit at Spring Grove, where I had the pleasure of tasting one of these Apricots; and I think it will prove an acquisition well worth cultivating. The black colour of the fruit, may, perhaps, prejudice some persons against it; but the

flavour, in my opinion, is very good ; and if it be considered, that the wood of 1799 was not well ripened, owing to the wet season, there is little doubt, that next year, if the season should be favourable, the flavour of the fruit will be greatly improved, and continue improving till the tree comes to maturity. The scantiness of the present crop of Apricots, Peaches, Nectarines, &c. may be attributed to the wood not being properly ripened last year.

For the accommodation of those who have small gardens, and yet wish to have a regular succession of fruit, we shall give abstracts of the larger selections; retaining those kinds only which are best adapted for that purpose; and of which one or more trees of a sort may be planted, according to the size of the garden, or the demand of the family.

*A Selection of Apricots for a small Garden.*

The Masculine; Roman; Orange; Breda; and Moor-Park.

*Of the Planting, Pruning, and Training of Apricots.*

The best time for planting Apricots is in Autumn, as soon as the leaf begins to fall. The person who goes to the nursery for the plants should make choice of those which have the strongest and cleanest stems; and if he can procure such as have been headed down (to use the phrase of the nurserymen), of two or three years' growth, they will bear and fill the walls much sooner than those which have not been so treated. He should make choice of trees with one stem; or, if they have

two, one of them should be cut off; for by planting those with two stems the middle of the tree is left naked, and, of course, one third of the wall remains uncovered.

I know that it is the practice of many to make choice of trees with the smallest stems; but these always produce weaker shoots than the others.

*On preparing the Borders.*

If the borders wherein the trees are to be planted be new, they should be made two feet and a half or three feet deep, of good light fresh loam. If the trees are to be planted in old borders, where the earth has been injured by the roots of the former trees, it will be necessary to take out the old mould at least three feet deep, and four feet wide, filling up the hole with fresh loam, and taking care to plant the trees about eight inches higher than the level of the old border, to allow for the sinking of the earth, that they may not be too deep in the ground: but this will be more fully treated of in the chapter on Pear-trees.

When the trees are planted, they should by no means be headed down till the month of April or May, when they begin to throw out fresh shoots. Strong trees should be cut a foot from the ground; and those that are weak, about half that length.

In backward seasons, they should not be headed down so early; never until the buds are fairly broken; always observing to cut sloping towards

the wall, and as near to an eye as possible, that the young leading shoot may cover the cut [*See PLATE I. Fig. 1.*]; which operation should be again performed in the next March or April. The shoots that are then thrown out must be trained horizontally to cover the wall. The number of these to be left ought to be from three to six on each side, according to the strength of the main shoot; taking care to rub off, with the finger and thumb, the fore-right shoots all over the tree, except a few which may be wanted to fill up the wall, near the body of it. [*See PLATE I. Fig. 1.*]

In the second year, the horizontal shoots must be shortened in the same manner, according to their growth; and so on every year till the wall shall be completely covered from top to bottom.

It is a frequent practice with some gardeners, to head down the trees at the time of planting; which very often proves fatal to them.

#### *Of old and decayed Trees.*

It has been the general practice to train wall-trees in the form of a fan, which occasions the sap to rise too freely to the top, leaving the lower part almost naked; so that scarcely one quarter of the wall is covered with bearing wood.

In that case, it will be necessary to cut down the whole of the tree, as near to the place where it was budded as possible; remembering always to cut it at an eye or a joint. If there should be any

young shoots on the lower part of the tree, it will be proper to leave them, training them horizontally, which will check the flow of the sap, and thereby render them much more fruitful.

Very frequently, when large branches have been cut off in a careless manner, and the wounds left to nature, the whole tree is infected with the gum and canker ; which, if not checked, will in a short time totally ruin it.

The best remedy in this case is, carefully to pare off the cankered part of the bark with a draw knife, or other convenient instrument. You will frequently find the white inner bark infected, which must also be cut away, till no appearance of infection remains ; this may be easily known by the brown or black spots, like dots made with a pen, of which not one must be suffered to remain.

All the branches so cut and pared should be immediately covered with the Composition in a liquid state ; the preparation and application of which will be particularly described in another place.

As we sometimes see walls with all the trees infected, it will in that case be most prudent to cut every other tree, leaving the rest for a supply of fruit till those which are cut begin to bear ; this will be in the second or third year.

When trees are in a very bad condition, they should be cut in a partial manner, taking off the worst branches first, particularly those in the

middle of the tree, always cutting as near to the graft as possible ; or every other branch may at first be taken out, leaving the rest to bear ; by which means there will be a supply of fruit while the other parts of the tree are renovating. It should be remembered, however, that all the cankered bark must be cut off without loss of time ; otherwise the new wood will be infected.

Old trees thus headed down will sometimes throw out very strong and vigorous shoots, which it may be necessary to top, as it will cause them to throw out side-shoots, and soon fill up the wall with fine bearing wood ; but they should never be suffered to have any fore-right spurs, except little dugs. The topping should be done in the beginning of June, which will cause the tree to produce fine bearing wood for the next year. Those trees must be pruned in March following, shortening the shoots from fifteen to six inches, but according to their strength, always leaving the strongest shoots longest.

Wherever the knife has been used, the Composition must be immediately applied.

After the fall of the leaf, it will be proper to unnailed the young shoots, leaving only a few to prevent the tree from being broken by the wind. By this method they will be more exposed to the sun and air, which will ripen and harden the wood much more speedily than if they be left nailed.

I have a great dislike to autumnal pruning of fruit trees ; of all kinds of stone-fruit in particular ; for by pruning at that season you seldom fail to bring on the canker ; and no fruit-trees are more liable to this disease than the Apricot. The reason is obvious ; the great acidity in these trees, the exposure of the wounds, and the dormant state of the sap, predispose to mortification ; whereas, in Spring, when the sap is beginning to flow, and will follow the knife, the lips will quickly grow. If the branches are small, a fresh bark and fresh wood will in one season completely cover the wound ; but if large, a time proportionate to their size will be occupied ; this process, however, is manifestly much accelerated by the application of the Composition, which excludes the air and wet from the air and sap-vessels of the tree.

It may now be proper to give a few directions for covering Apricots, to prevent the blossom from being destroyed by frosts, cutting winds, &c.

In severe weather, they ought to be covered before the flowers begin to expand ; for I have often seen the blossoms drop off before they opened.

The best covering is old fish-nets, which should be put on three-fold ; and if a few branches of dry fern are stuck in among the branches before the nets are put on, they will assist greatly in breaking the force of the high winds. It is a

common practice, to cover with mats in the night, and to take them off in the day; but this, by frequent exposing the trees to the cutting winds, does more harm than good. Another practice is, to cover with branches of spruce-fir and yew; but these, being too close, encourage a blight, and cause the leaves of the trees to curl, and the shoots to break very weak; whereas the nets admit a free circulation of the air, and at the same time break the force of the wind. When it happens to rain or snow in the fore-part of the night, and freeze towards the morning, we find the drops hanging in icicles on the meshes, while the tree is almost dry.

When the shoots become pretty long, and the leaves expand to cover the fruit, it will be necessary to keep the net clear from the tree, by placing forked sticks, from six inches to a foot long, between it and the wall; this will prevent the shoots and leaves from growing through the net. The forked end of the sticks should rest against the meshes of the net.

A few trees for an early supply may be planted on a South aspect, according to the size of the garden, and the demand there may be for the supply of the family; but a West aspect is far preferable for the general crop. Those who wish for a late supply may have some trees planted on an East aspect.

The Breda is the best and the richest flavoured for a standard, although the Brussels is frequently

preferred: but I would by no means recommend planting more than three trees of each sort in a garden, as standards; as it is not one year in ten that a tolerable crop is produced from them.

The Breda, the Brussels, and the Moor-Park, should always be planted on an East or West aspect.

## CHAPTER II.

## OF PLUMS.

*Different Sorts of Plums cultivated in England. — Of Plant-heading and Training them. — Of Standards in Orchards, and Dwarfs in Gardens. — The Management of old decayed Trees.*

THE Plum is generally supposed to be a native of Asia, and the Damascene to take its name from Damascus, a city of Syria.

This genus of plants is arranged by Linnæus in the twelfth class of his System, Icosandria Monogynia; and is named *Prunus Domestica*.

*The Names and Qualities of those Plums which are commonly cultivated in England, with their Time of ripening.*

1. JAUNEHATIVE; *White Primordian*. Duham. n. 1. t. 1. Pom. Franc. 1. p. 120. t. 3. f. 1. Pom. Aust. t. 192. f. 1. Poit. et Turp. Fr. t. 149. This is a small long plum, slightly cleft; the skin is of a yellowish-white colour; the flesh mealy, the juice is sugary, and sometimes a little musky. It bears well, and ripens in the latter end of July, or beginning of August. One tree will be sufficient for a garden.

2. PRECOCE DE TOURS. *Duham. n. 2. Pom. Aust. t. 177. f. 2. Poit. et Turp. Fr. t. 128. Hooker Pom. Lond. t. 34.* This is a small oval fruit, slightly cleft; the skin is of a dark purple colour, covered with a fine blue meal; the flesh is a dull greenish yellow, tender, juicy, and well-flavoured. It is a good bearer, and ripens in the end of July.

3. ROYALE DE TOURS. *Duham. n. 17. t. 20. f. 8. Pom. Franc. 1. p. 123. t. 4. f. 3. Pom. Aust. t. 184. f. 2. and t. 191. f. 1. Poit. et Turp. Fr. t. 13.* This is a large roundish plum, with a well-marked but slight cleft; the skin is of a fine deep violet, covered with much bloom, and sprinkled with very small golden-yellow spots; on the shaded side it is more of a bright red than violet; the flesh is yellow, inclining to green, fine and very good. The juice plentiful, sugary, and high-flavoured. It ripens in the end of July, or beginning of August, and is esteemed an excellent plum.

4. EARLY BLACK DAMASK. *Langley Pom. t. 20. f. 3.* This, commonly called the *Morocco plum*, is a middle-sized, round, dark, black fruit, covered with a violet bloom; the flesh is yellow, juicy, somewhat acid, but well-flavoured. It ripens about the beginning of August.

5. LATE OR SMALL BLACK DAMASK. *Duham. n. 9. t. 20. f. 4. Pom. Franc. 1. p. 125. t. 5. f. 5. Pom. Aust. t. 178. f. 2.* This is a small fruit, not cleft; the skin of a deep violet colour, almost black, with much bloom, and not easily peeling

from the flesh ; the flesh is yellowish next the sun, and green on the other side ; the juice plentiful and good, sometimes a little acid. It is a good bearer, and ripens about the latter end of August.

6. GREAT DAMASK OF TOURS. *Duham. n. 4. Pom. Franc. 1. p. 121. t. 3. f. 2. Pom. Aust. t. 184. f. 1.* This is a middle-sized oval plum ; the skin is of a deep bluish colour, covered with much bloom, and adheres to the flesh ; the flesh is orange or yellow, firm, and the juice sugary. It is ripe in August.

7. ORLEANS ; *Red Damask. Langley Pom. t. 20. f. 4. Pom. Franc. 1. p. 126. t. 5. f. 6. Pom. Aust. t. 180. f. 1.* This is a large well-known fruit, of a middle size, round, of a deep red colour, mixt with blue or violet next the sun, and of a brighter red and greenish on the shaded side, with bloom, slightly cleft ; the flesh is pale yellow or whitish, firm, and the juice rich, but somewhat acid ; the stone quits the flesh clean. It is a plentiful bearer, and ripens in the end of August.

8. ORLEANS, WILMOT'S NEW EARLY. *Hort. Soc. Trans. 3. p. 393. t. 14.* This is middle-sized, round, slightly cleft ; the skin of a dark purplish tint next the sun, and pale red on the shaded side, covered with a fine blue meal, and peels readily from the flesh ; the flesh of a rich greenish yellow, with an amber tint when ripe, softer and more juicy than the Orleans, of excellent flavour, sweet combined with pleasant acid ; the stone small, and parts clean from the

flesh. It ripens three weeks before the Orleans, and as early as the *Precoce de Tours* and *Morocco* plums.

9. *FOTHERINGHAM; Sheen Plum. Langley Pom. t. 20. f. 6.* This is an excellent plum, large, long, and deeply cleft; the skin is of a deep red colour, a little spotted, and covered with a thin violet bloom; the flesh white, firm, crisp, parts freely from the stone, which is large, and the juice rich: there is hardly any plum that excels it. Ripens in end of August.

10. *RED PERDRIGON. Duham. n. 22. t. 20. f. 6. Pom. Aust. t. 172. f. 2.* This is a middle-sized plum, of an oval shape, and not cleft: the skin is of a fine red, inclining to violet, sprinkled with very small brownish yellow spots, and has much bloom; the flesh is bright yellow next the sun, and green on the other side, firm, sweet, and juicy. It ripens the end of August or beginning of September, and is much esteemed.

11. *VIOLET, or BLUE PERDRIGON. Duham. n. 21. t. 9. Pom. Franc. 1. p. 148. t. 17. f. 31. Pom. Aust. t. 197. f. 1.* This is an oval oblong plum, slightly cleft; the skin is thick, of a fine violet, inclining to red, finely powdered with white silvery meal, and marked with little golden yellow spots; the flesh is yellowish green, adhering to the stone, and of a rich sugary high flavour. It ripens in August.

12. *WHITE PERDRIGON. Brignole. Duham. n. 20. t. 8. Pom. Franc. 1. p. 145. t. 15. f. 27.*

*Pom. Aust. t. 193. f. 1.* This is a small fruit, rather longish, with a slight cleft; the skin is thick, of a whitish green, marked with little red spots towards the sun, and covered with a white meal; the flesh is white, a little green, transparent, and melting, though firm. It has a perfumed flavour, and is excellent eaten raw or made into sweetmeats. The plums dried in the sun, called *Brugnolles*, are made from this plum, and bear the name of the village in Provence, whence they come. It ripens the beginning of September.

13. NECTARINE PLUM. *Caledonian, Goliath.*  
*Hooker Pom. Lond. t. 39.* This is a very large fruit, nearly round, a little flat at each end, and slightly cleft; the skin is acid and pungent, of an intense red, inclining to a dull purple colour when ripe, with a slight meal sometimes on it; the flesh is greenish yellow, firm, but well flavoured, and parts readily from the stone. It bakes well, ripens on standards in August and September, but much earlier on a wall.

14. COE'S GOLDEN DROP. *Bury Seedling.*  
*Hooker Pom. Lond. t. 14.* This is an oblong, or rather bell-shaped fruit, the broad end irregular, one side projecting rather beyond the other, and slightly cleft; the skin greenish yellow, spotted next the sun with violet and crimson, the gold colour of the flesh is seen through the skin when fully ripe, and has a rich appearance; the flesh is fine, yellow, firm, and juicy. It ripens in September, and will keep to the middle of December. It

bears well on standards, but succeeds best against a wall. It may be recommended as an excellent late plum.

15. RED IMPERIAL; *Red Bonum Magnum*. *Duham. n. 32. t. 15. Pom. Franc. 1. p. 127. t. 6. f. 7. Pom. Aust. t. 172. f. 1.?* This is a large oval-shaped plum, of a deep red colour, covered with a fine bloom, and bluish next the sun; the flesh is yellow, soft, and juicy, but of a moderate relish. It is a great bearer, and mostly used for baking: ripens about the latter end of September.

16. WHITE IMPERIAL; *White Bonum Magnum*. *Egg Plum, White Holland, Mogul. Duham. n. 35. Pom. Aust. t. 175. f. 1.* This is a very large oval fruit, of the shape and almost the size of a turkey's egg; the skin is white, thick, adhering to the flesh; of a yellowish colour, slightly tinged with red next the sun; the flesh is firm, white, dry, and the juice acid and unpleasant. It is like the red, mostly used for baking or sweetmeats. It adheres closely to the stone, is a great bearer, and ripens about the beginning of October.

17. LA ROYALE. *Pom. Aust. t. 186. f. 1. Hooker Pom. Lond. t. 47.* This is a fine plum, equal to the Green gage, but a shy bearer. It is large, round, a little oval next the stalk, and slightly cleft; the skin is thin, of a dull reddish purple, and covered very thickly with a pale blue, or grey meal; the flesh is dull yellow, or dark amber tint, very melting, sweet, and full of rich juice. The stone

comes from the flesh when fully ripe. It ripens in September. The *La Royale* of *Duhamel*, n. 24. t. 10. appears to be very different from this plum.

18. **LITTLE QUEEN CLAUDE.** *Duham.* n. 26. *Pom. Franc.* 1. p. 131. t. 8. f. 11. *Pom. Aust.* t. 189. f. 3. This is a small round fruit, flat at the stalk, and deeply cleft; the skin is of a whitish-green colour, much covered with a pearl coloured bloom; the flesh is firm, white, a little dry, and the juice sugary and well-flavoured, but sometimes it is a little acid. It ripens in September. This is very different from the next in leaves, wood, and fruit.

19. **GREAT QUEEN CLAUDE; Dauphine.** *Abri-cot vert. Verte bonne.* *Duham.* n. 25. t. 11. *Pom. Franc.* 1. p. 130. t. 7. f. 10. *Pom. Aust.* t. 193. f. 2. *Poit. et Turp. Fr.* t. 81. This is a middle-sized round fruit, flat at both ends, slightly cleft; the skin adheres to the flesh, it is thin, of a green colour, marked with grey spots, and sprinkled with red next the sun, and covered with a very light bloom; the flesh is greenish-yellow, very fine, delicate, melting; the juice plentiful, sugary, and of an excellent taste. The stone adheres in parts to the flesh. It ripens in August and September, and is a good bearer. It is esteemed by the French as the best eating plum without any exception. By many persons this is called the Green Gage.

20. **GREEN GAGE.** *Hooker Pom. Lond.* t. 38. This is a round plum, rather compressed at both

ends, varying in size, with a slight cleft the whole length of the fruit; skin pale cinereous green, tinted with yellow and faint purple, spotted with red on the side next the sun, and covered with a very delicate meal; flesh yellowish green, very fine, melting, and full of rich and well-flavoured juice. The stone adheres slightly to the flesh. It ripens in August and September.

There are many varieties of this plum differing from each other, in the size, colour, and quality of the fruit. It may be reproduced from the stone.

21. DRAP D'OR; *Cloth of Gold*. *Duham. n. 30. Pom. Franc. 1. p. 129. t. 7. f. 9. Pom. Aust. t. 187. f. 1.* This is a good plum, and a plentiful bearer; of a middle size, nearly round, with scarce any cleft, with a remarkable dimple at each end, and a short stalk; the skin is of a bright yellow colour, and spotted with red next the sun; the flesh is yellow, melting, and transparent; the juice sugary and very high flavoured; the stone is small, and does not entirely part from the flesh. It is ripe about the end of September.

22. CHESTON. *Langley Pom. t. 23. f. 2.* This is a rich plum, and a great bearer. It is of an oval shape, covered with a light violet bloom, and of a dark blue colour; the flesh is dark yellow, and full of a sweet and agreeable juice. It is ripe about the end of September.

23. APRICOT PLUM. *Duham. n. 28. t. 13. Pom.*

*Franc.* 1. *p.* 132. *t.* 8. *f.* 12. *Pom. Aust.* *t.* 173. *f.* 1. This is a large round plum, deeply cleft; the skin of a pale yellow colour, and white bloom, marked with brownish red next the sun; the flesh is yellow, firm, dry, musky, and sweet. It is ripe the beginning of October.

24. MAITRE CLAUD. *Langley Pom.* *t.* 23. *f.* 6. This is a large round plum, the skin of a bright yellow, with some spots of dark red next the sun, and covered all over with a thin white bloom; the flesh is pale yellow, firm, parts from the stone; the juice is very brisk, though sweet. It is a good bearer, and accounted among the best white plums that we have. It ripens about the beginning of October.

25. MYROBALAN; *Cherry Plum.* *Duham.* *n.* 46. *t.* 20. *f.* 15. *Pom. Franc.* 1. *p.* 137. *t.* 11. *f.* 18. *Pom. Aust.* *t.* 192. *f.* 2. This is a round middle-sized fruit; the skin is very hard, smooth, of a light cherry colour, sprinkled with very small whitish spots; the flesh is bright yellow and transparent, but becomes mealy when the fruit is full ripe. It is not much esteemed: ripens about the beginning of September. The tree is frequently planted for ornament, as it blossoms early.

26. MIRABELLE. *Duham.* *n.* 29. *t.* 14. *Pom. Franc.* 1. *p.* 124. *t.* 4. *f.* 4. *Pom. Aust.* *t.* 174. *f.* 2. *Poit. et Turp. Fr.* *t.* 47. This is small, round, rather long, not cleft; the skin is of a whitish yellow or amber colour when ripe, and sometimes has

a little red next the sun ; the flesh firm, yellow, a little dry, yet full of juice, and excellent for sweetmeats. It bears well, and is ripe about the beginning of September.

27. LARGE WHITE DAMASK. *Duham. n. 7. t. 3. f. 2. Pom. Franc. 1. p. 139. t. 12. f. 20.* This is a middle-sized oval plum, of a pale yellow colour outside, and covered with white bloom ; the flesh is firm, yellow, and well tasted. It is much esteemed for sweetmeats. It ripens about the beginning of September.

28. ROCHE-CORBON ; *Red Diaper Plum. Duham. n. 37. t. 20. f. 12. Pom. Franc. 1. p. 151. t. 17. f. 33. Pom. Aust. t. 185. f. 2.* This is a large long fruit, not cleft ; the skin of a reddish cherry colour, spotted with brown, and easily strips off ; the flesh is yellow, fine, firm, adheres to the stone, and of a very high flavour, and very sugary. It ripens about the beginning of September.

29. SAINT CATHERINE. *Duham. n. 43. t. 19. Pom. Franc. 1. p. 150. t. 17. f. 32. Pom. Aust. t. 186. f. 2. Hooker Pom. Lond. t. 24.* This is one of the best plums, and is much used for confectionery : it is also very good for the table, having a rich sweet juice, and is a good bearer, hanging the longest of any on the tree. I have had them in gathering six weeks. The fruit is of a middle size, oblong, narrow at the stalk, broad and flattened at the other end, and slightly cleft ; the skin is of a pale greenish yellow, covered with

a fine meal, and beautifully spotted with red when fully ripe; flesh yellow, soft, sweet, and of a fine flavour. The stone adheres partly to the flesh, but when fully ripened, it parts from it. It ripens about the latter end of September.

30. VIOLET, or BLUE IMPERATRICE; *Empress*. *Duham. n. 39. t. 18. Pom. Aust. t. 200. f. 2. Hooker Pom. Lond. t. 4.* This is a middle sized fruit, longish, pointed at the stalk, and round or broad oval at the other end, slightly cleft, and one side generally irregular. The skin is of a fine violet colour, covered with a light blue meal: the flesh firm, delicate, inclining to yellow next the sun, and green on the other side. It has an agreeable flavour and ripens about the middle of October. This is one of the latest plums, and should not be gathered till it begins to shrivel; it will then eat like a sweetmeat, and makes a great addition to the table in the latter end of October and beginning of November.

31. MONSIEUR; *Wentworth, Dame Aubert, Grosse Luisante. Duham. n. 41. t. 20. f. 10. Pom. Franc. 1. p. 133. t. 9. f. 13. Pom. Aust. t. 188. f. 1. Poit. et Turp. Fr. t. 71.* This is a large oval plum: the skin of a yellow colour next the sun, and inclining to green on the other, covered with a very white meal; it is thick but easily strips off the flesh. The flesh is yellow, and the juice sugary, but becomes mealy when full ripe. It resembles the Bonum Magnum; it ripens the beginning of October, and is good for preserving, but too sharp to be eaten raw. It bears well.

The *Monsieur* of *Duhamel*, n. 15. t. 7., is quite a different plum.

82. WINESOUR. This is a Yorkshire plum, and one of the best for preserving. It is oblong, somewhat larger than a damson, of a dark violet or black colour when ripe. The flesh is yellow, juicy, adheres to the stone, and has an agreeable acid taste. It is a good bearer, and will succeed on any soil, but best on lime-stone or gravel. It is ripe in October.

83. DAMSON PLUM. A fine large sort of damson from Shropshire, raised from suckers or stones, is an abundant bearer, of a rich flavour, and is good for baking or preserving. It ripens the latter end of September, and continues till near the latter end of October.

*On the Choice, Planting, Pruning, &c. of Plum-Trees.*

When you choose your trees, let the same directions be observed as in the choice of Apricots. Choose clean straight plants with single stems; as those with two never make handsome trees either for walls or standards. Manage the border as before directed for Apricots; digging the holes the same width and depth, and loosening the bottom; then fill up the holes with fine fresh loam, or the mould that was used the preceding year for melon and cucumber beds; and be careful to keep the mould a proper height above the border, and the roots of your trees as near the surface as possible, spreading them horizontally. If there are any tap-roots, they should always be cut off, as should also the fine hairy

roots, as they are liable to get mouldy and rot, and thereby bring on a putrefaction of the mould about the root of the tree. If the roots are not spread near the surface of the ground, it will prevent the sun and air from penetrating to them; and the fruit, of course, will not have so fine a flavour.

Never cut the stems of young plum-trees when first planted, but leave them till the buds begin to break; then you may head them down to five or more eyes, always observing to leave an odd one for the leading shoot: remember to cut sloping towards the wall, and as near to an eye as possible. Thus managed, the shoots will soon fill the wall with fine wood. If you find that some of the shoots are too luxuriant, you may pinch the tops off with your finger and thumb, about the beginning of June, in the first year after planting; by doing which you will obtain plenty of wood to fill the bottom of the wall. A great deal depends on the first and second year's management of your trees.

The distance from each other at which plum-trees should be planted against a wall depends on the height of the wall. If the wall be ten feet high, which is the common height, they may be planted at eight yards distance from tree to tree; but if the wall be twelve feet high, or more, seven yards will be sufficient. For my part, I prefer a wall of ten or twelve feet, which will be found high enough, if the branches are trained

horizontally ; by which means your trees will be much more fruitful, and not grow so luxuriantly.

By training an upright shoot on your plums, as directed for pears, you will get fine kind shoots from the sides. The leading shoot should be shortened, leaving it from one to two feet long, according to its strength. If the leading shoot be very strong, you may top it twice in the summer, as directed for pears, and at the same time that you top them ; repeating the same every year till the wall is filled to the top. I would always recommend, where it is convenient, to allot one wall for plums and another for cherries, as they always thrive best by themselves.

As you will have plum-trees to spare, that were planted between pear-trees, when they begin to meet, they should be planted against another wall, or planted out as dwarf standards. Those which you intend for standards should be prepared in the following manner : The year before you mean to transplant them, cut in the side-shoots at different lengths, from one foot to three, according to the size of the trees ; suffering them to grow rude all the summer, neither nailing in nor cutting the side and foreright shoots. Some time during the winter open the ground round their roots, and cut in the strong ones (which will cause them to put forth fine young fibres) ; then fill in the earth. In the following autumn, or during the winter (the sooner the better), you may transplant them out as stand-

ards.\* If you intend to plant them against a wall, never cut the side-shoots, but only the roots ; by this method the trees will bear fruit the first year after transplanting, and there will be a great saving of time and money. I have often transplanted old plum-trees that have been headed down, that have made very fine roots, which I have divided, and thereby obtained four or five trees from one, cutting them so as to form them into fine heads. Some that were transplanted in 1798 were in full blossom in 1799, producing some fruit, and this year (1800) bearing a full crop.

The ground in the borders and quarters where fresh trees are to be planted should be well trenched, two spits deep at least, to give the roots room to run into the fresh-stirred ground.

When you plant trees without stirring the mould, they seldom thrive well.

When plum-trees are planted for standards in an orchard which is to be kept for grass, they should be in rows at the distance of twenty yards from each other. If in the kitchen garden for standards, I would always recommend the planting of dwarfs. You may train the tree up to have a stem of about three feet high, at the distance of seventeen yards.

\* In transplanting of trees, especially large ones, I consider it to be of great consequence, that they be placed in the same position (that is, having the same parts facing the same points of the compass) as formerly. If you take notice when a tree is cut down, you will find that three parts in four of the growth are on the North side.

If the garden is laid out with cross-walks, or foot-paths, about three feet wide, make the borders six feet broad, and plant the trees in the middle of them. In the royal gardens at Kensington, which are very long and narrow, and where the winds are very hurtful, I have planted two rows of apple-trees, intermixed with other fruit-trees, alternately, one row on each side of the middle walk (which runs the whole length of the garden), at the distance of seventeen yards from each other. I have also made cross-walks of three feet broad, at the distance of seventy yards, with borders on each side six feet wide, having two rows of trees in each border, about twelve or fourteen feet asunder. These dwarf-trees are very useful in breaking the force of high winds, and are at the same time of such a height that a man standing on the ground may gather the fruit. As plum-trees may be planted in the same manner, and for the same purpose as the above, you can have the quarters clear for crops for the kitchen, and a free air will be admitted, which you can never have if you plant espaliers: dwarf standards can be kept to what size you please; they look much handsomer than espaliers, and produce a greater quantity of fruit.

*On pruning and restoring old and decayed Plum-Trees.*

I have restored plum-trees, some of which were so far decayed as to have only from one to two or

three inches of bark left; they are now completely filled up with sound wood, with large heads, which at four years growth filled a wall sixteen feet high, and are at this time full of fine fruit; some of the stems are several inches in circumference, bearing treble the crops produced by young trees that have been planted three times as long as they have been headed down.

Where the trunks are become hollow, I always cut out all the loose rotten parts, and also examine the roots, cutting off what is rotten, injured, or decayed. This method should be pursued with all hollow and decayed trees; and, if properly executed, they may be so completely filled up, as scarcely to leave a mark behind, even where the wood is totally decayed.

I have had shoots from plum-trees which have been headed, that have grown upwards of seven feet long, and as large as a walking-stick, in one summer; this should never be suffered; but they should be pinched off with the finger and thumb, in the beginning of June, close to an eye or a bud; unless the wall be filled to the top; in which case they should never be cut while they continue to bear handsome fruit. Before they begin to cease from bearing, you must always begin with shortening every other shoot, leaving them only from six inches to a foot long, and nail them in till the second year, taking care to rub off the superfluous and strong foreright shoots; by that time they will begin to bear: then cut

out the others that have done bearing: by this method you will keep the trees in a flourishing state. When the branches are thus managed, they will frequently throw out small dugs, or foreright shoots, about an inch or two long, which will flower next year. They should never be shortened till after the fruit is set and become about the size of a large pea; by that time the leaves will have covered the fruit, and be able to protect it from the inclemency of the weather. You may now shorten these shoots close to the fruit, which will leave them from one to two inches long. This method I have practised with great success for several years. By leaving these short foreright shoots, the fruit is protected till it is out of danger of being killed by the frost, or stunted by the cold North and North-west winds that happen about the latter end of March and beginning of April. The cold chilling rain and snow, which are also very injurious to the fruit, will be thrown off by the branches standing out from the trees. I by no means like to see great spurs standing out from the wall; for they are always sure to be injured by the frost and cold winds. [See PLATE II. *fig. 2. and 3.*] When the shoots are left naked, I have often seen the plums turn yellow, and drop after they have grown to a considerable size, from their being exposed to the cold frosty winds and rain.\*

\* In cold and frosty weather, Plums must be covered in the same manner as Apricots.

Plums are more tender than any other sort of stone fruit, owing to the flower-cup dropping sooner than that of Peaches, Nectarines, &c. They are very liable to decay, after cutting off large limbs or branches, which always brings on the gum and canker, if it be left to nature to perform the cure. I would, therefore, recommend the application of the composition (in the same manner as directed for other sorts of fruit-trees) to every shoot where the knife touches, as soon as the trees are cut and nailed.

If you wish your fruit to be large and fine, you must take care to thin it where it is too thick; but that must not be done too soon, lest it should be pinched by the cold. The fruit ought to be of the size of a small marble, and well sheltered by the leaves, before you attempt to do this. Never pull off the leaves that shelter the fruit, till it is full-grown and begins to turn. This will be more fully treated of, when we come to the management of Peaches and Nectarines.

I have taken up several old trees from the walls when they have grown too near each other, and planted them out as standards, at the same time shortening their branches to form handsome heads, which are now full of fine fruit. These trees would, by any other person, have been thrown to the faggot-pile.

## CHAPTER III.

## OF PEACHES.

*Different Sorts of Peaches described. — Of the Soil. — Of planting, heading, pruning, and training. — Method of making Incisions. — Of covering Peach-Trees, watering, &c.*

THE Peach is probably a native of Persia, and was introduced thence into Europe. It belongs to the twelfth class of Linnæus, Icosandria Monogynia; and is named *Amygdalus Persica*. It was cultivated here in 1562, according to Turner's Herbal, *part. 2. fol. 48. verso*.

*The following are the Sorts cultivated in this Country.*

[N.B. Those marked with an Asterisk (\*) adhere to the stone, and are by the French called Pavies.]

1. WHITE NUTMEG. *Duham. n. 1. t. 2. Pom. Franc. 2. f. 324. t. 7. f. 1.* This is a small white Peach, with seldom any red; the flesh is white to the stone, which is small: and the juice is sugary and sometimes musky. It is only esteemed as being first ripe. It is in eating in July, and soon grows mealy.

2. RED NUTMEG. *Duham. n. 2. t. 3. Pom. Franc. 2. p. 326. t. 7. f. 2.* This is a great bearer,

and valued for its early maturity. It is larger than the white, somewhat round, of a bright vermillion colour on the side next the sun, and clear yellow on the other; the flesh is white, melting, and a little tinged with red on the sunny side, but without any red veins next the stone; it has a fine musky flavour. This Peach is much esteemed, and ripens about the beginning of August.

3. EARLY PURPLE AVANT. *Brown Nutmeg. Avant Pêche jaune. Duham. n. 4.* This is a small fruit. On the side next the sun the skin is tinged with a deep red brown, and on the other side with a yellow gold colour, covered all over with a thick ruddy down: the flesh is golden yellow, except near the stone, and sometimes under the skin, where it is a carmine red. It is fine and melting, with a sugary and rich juice; it has an agreeable flavour, and ripens in August, but is apt to be stringy.

4. SMALL MIGNONNE. *Duham. n. 3. t. 4. Pom. Franc. 2. p. 326. t. 7. f. 3. Poit. et Turp. Fr. t. 101.* This is a small round fruit, with a thin skin, very red on the side next the sun, and yellowish white on the other; the flesh is firm, white, and has sometimes red veins next the stone; it has a rich vinous juice, and is ripe about the middle of August.

5. WHITE MAGDALEN. *Montagne blanche. Duham. n. 8. t. 6. Pom. Franc. 2. p. 328. t. 8. f. 5.* This is a middle-sized round Peach, deeply cleft on one side, with a thin skin readily peeling off; it is

12. **ROYAL KENSINGTON.** This is one of the best Peaches we have, of a high red colour next the sun, and of a yellowish colour next the wall. It is a good bearer, and not liable to be blighted; the flesh is full of rich juice. It ripens about the latter end of August or beginning of September. \*

13. **LARGE FRENCH MIGNONNE.** *Duham. n. 14. t. 10. Pom. Franc. 2. p. 333. t. 9. f. 7. Poit. et Turp. Fr. t. 135.* This is a beautiful large Peach, very round and deeply cleft, with a thin skin covered with a fine satin down, and easily parts from the flesh; it is a bright green, inclining to yellow on the shaded side, but deep brownish-red next the sun: the flesh is fine, delicate, melting, and juicy; white, except under the skin next the sun and round the stone, where it is marbled with bright red; the stone is very small, and comes from the flesh. It has a sweet, vinous, high-flavoured juice. This is one of the best French Peaches, and is ripe the latter end of August.

14. **GRIMWOOD'S NEW ROYAL GEORGE.** *Hooker Pom. Lond. t. 41.* This fruit is round, middle-sized, rather flat, one side generally longer than the other and deeply cleft: the skin is of a dark

\* This handsome Peach, I am told, was with some others sent from France to Her Majesty, upwards of twenty years ago. I have therefore taken the liberty to give it the above name, that it may not be confounded with Mr. Grimwood's Kensington Peach. When I came to Kensington, in 1784, I found it mentioned in the Catalogue as a new Peach from France.

red colour, with streaks of deeper red next the sun; flesh pale yellow, with a few streaks of red from the skin, and blotches of a fine carmine round the stone. It has a sweet, vinous juice, of excellent flavour. It ripens the end of August to middle of September. \*

15. MONTAUBAN. *Langley Pom. t. 28: f. 4.* This is a middle-sized roundish fruit, with a cleft on one side, of a deep red inclining to purple next the sun, but pale green towards the wall. It has a mild melting flesh, white to the stone, with sometimes a little red. It has a rich juice; and the tree is hardy and a plentiful bearer. It is ripe the latter end of August.

16. EARLY CHEVREUSE. *Belle Chevreuse. Duham. n. 17 & 18. t. 13. Pom. Franc. 2. p. 336. t. 10. f. 8.* This is a good peach, of a longish shape, slightly cleft: the skin is of a yellow colour, mostly all over, except next the sun, where it is a beautiful red. It is covered with a thickish down: the skin does not part from the flesh easily, except when full ripe: the flesh is whitish-yellow, slightly tinged with red under the skin on the sunny side, and marbled with rose-colour round the stone: the juice is rich and sweet. It ripens about the beginning of September, and is a plentiful bearer.

17. CHANCELLOR. *Duham. n. 19. Pom. Franc. 2. p. 342.* This much resembles the Chevreuse. It

\* This is said to be the same as the large French Mignonne.

is one of the best sort of Peaches. The skin is very thin, and of a fine red colour next the sun; the flesh is white, melting, red at the stone, and the juice is very rich and excellent. It ripens about the middle of September.

18. RED MAGDALEN. *Duham. n. 10. t. 7. Pom. Franc. 2. p. 339. t. 10. f. 9. Poit. et Turp. Fr. t. 26.* This is a large round fruit, sometimes flat at the stalk, of a deep red colour next the sun; the flesh white, with red veins at the stone, and full of a rich sugary juice, of excellent flavour. It is a very good Peach, and ripens the beginning of September.

19. \* EARLY NEWINGTON. *Smith's Newington. Pavie blanc. Duham. n. 9. Langley Pom. p. 101. t. 28. f. 4. Pom. Franc. 2. p. 342. t. 12. f. 11.* This is middle-sized, roundish; the skin of a beautiful red colour next the sun, but white or pale green on the other: the flesh is firm, like all the Pavies, white, juicy, adhering to the stone, where there are streaks of red. It is full of a plentiful juice, which is very vinous when the fruit is full ripe. It ripens the beginning of September.

20. MALTA. *Italian. Belle de Paris. Duham. n. 11. Pom. Franc. 2. p. 343. Langley Pom. 107. t. 33. f. 2.* This is a middle-sized, flattish Peach, and nearly round; the skin is of a fine red colour next the sun, marbled with a deeper red, and bright green on the shaded side; it has a white melting flesh, a little musky, and red at the stone.

- The tree is a good bearer, and the fruit ripens the beginning of September. It much resembles the White Magdalen in leaves, flowers, and fruit. It may be raised from the stone.

21. NOBLESSE. *Langley Pom. t. 28. f. 3. Hooker Pom. Lond. t. 2.* This is a large Peach, generally round, sometimes longish, with a very small nipple at the end. The skin is marbled with red and dull purple, when fully exposed to the sun; it is thin, easily peels off the flesh, and in very hot weather is subject to blister: the flesh is very white, with some faint yellow in it, and white to the stone; the juice is sweet, melting, and very rich in a good season. The tree is hardy, easy to be trained, a good bearer, and forces well. It ripens the beginning of September.

22. BOURDINE. *Boudin, Narbonne. Duham. n. 16. t. 12. Pom. Franc. 2. p. 347. t. 15. f. 16. Poit. et Turp. Fr. t. 147. Hooker Pom. Lond. t. 16.* This is a very fine large fruit, nearly round, and deeply cleft; the skin is of a fine dark red colour, easily parts from the flesh, and is covered with a very fine down; the flesh is fine, melting, whitish yellow, except near the stone, where it is very red, and sometimes that red extends into the flesh; the juice is rich and vinous, without any of that sharpness in it which sometimes diminishes the value of the large Mignonne. The tree is hardy, and a good bearer, especially when old, and the fruit highly esteemed. It will do very well in standards, and produce plenty of good fruit. It

may be raised from the stone without budding. The fruit ripens about the middle of September.

23. ADMIRABLE. *Duham. n. 29. t. 21. Pom. Franc. 2. p. 348. t. 16. f. 17.* This is a very large, round, beautiful Peach, slightly cleft; the skin is finely coloured with red towards the sun, and bright yellow or straw colour on the shaded side; the flesh is firm, white, melting, pale red next the stone. The juice is sweet, sugary, and of an exquisite taste. It ripens about the middle of September.

24. BELLEGARDE. *Galande. Duham. n. 28. t. 20. Pom. Franc. 2. p. 341. t. 11. f. 10. Poit. et Turp. Fr. t. 139. Hooker Pom. Lond. t. 8.* This is a very large fruit, roundish, rather more in breadth than length, and slightly cleft; the skin is tinged all over with a deep red, inclining to a purple colour towards the sun; it is hard, adheres closely to the flesh, and is covered with a very fine down; the flesh is whitish, with a tinge of very pale yellow, of a rose colour at the stone, melting, and full of a rich vinous juice. It ripens about the beginning or middle of September. It forces well, and is one of the best peaches for our climate.

25. ROSANNA. *Purple Alberge. Langley Pom. t. 27. f. 3. and t. 30. f. 5. Duham. n. 6.* This is of a fine purple colour next the sun; the flesh is yellow, red at the stone, and has a rich vinous juice. It is reckoned a good Peach, and is ripe about the middle of September.

26. \* LISLE. This is of a middle size, roundish, and of a fine violet colour next the sun ; the flesh is pale yellow, melting, adheres to the stone, where it is very red. It is full of a vinous juice. It ripens about the middle of September.

27. NIVETTE. *Duham. n. 37. t. 28. Pom. Franc. 2. p. 358. t. 21. f. 25.* This is a large fruit, round; and somewhat longish; the skin is firm, adheres to the flesh, except when full ripe. It has a greenish look, but when perfectly ripe turns yellow, except on the shaded side, where there remains a tinge of green. It is washed with bright and faint red, and sprinkled with deep red spots. It is covered with a fine white down, like velvet, which easily rubs off with the hand; the flesh is white, yet juicy, inclining to green, with veins of bright red next the stone. It is melting, and full of a rich sugary juice; sometimes it has a little sharpness. It is an excellent Peach, and ripens about the middle of September.

28. \* OLD NEWINGTON. *Langley Pom. p. 104. t. 31. f. 1.* This is a large, fine, round fruit, of a delicate red colour next the sun, but whitish on the other side; the flesh is firm, whitish yellow, deep red at the stone, has a fine high vinous tasted juice, and is esteemed a good Pavie. It ripens about the latter end of September.

29. RAMBOUILLET. *Rumbullion. Langley Pom. t. 33. f. 3.* This is pretty large, longish, and deeply cleft; of a fine red colour next the sun, and yellow on the shaded side; the flesh is bright

yellow, melting, deep red at the stone, and the juice vinous and rich. It ripens about the end of September or beginning of October.

30. ROYALE. *La Royale. Duham. n. 33. t. 24. Pom. Franc. 2. p. 357. t. 20. f. 24.* This fruit in part resembles the Admirable and the Teton de Venus. It is large, nearly round, and slightly cleft. It has often swellings on it like warts: the skin is covered all over with a whitish down, is deeper coloured than the Admirable: on the side next the sun, it is washed with bright red, charged with a deeper red; on the shaded side it is almost green, inclining to yellow, when full ripe: the flesh is fine, white, except near the stone, where it is redder than the Admirable. Sometimes it has a slight tinge of red under the skin on the sunny side: the juice is sugary and high-flavoured. It ripens the end of September.

31. SUPERB ROYAL. This is a fine large Peach, of a red colour towards the sun, and pale on the other side. It ripens in September.

32. \* BELLE DE VITRY. *Late Admirable. Bellis. Duham. n. 34. t. 25. Pom. Franc. 2. p. 355. t. 19. f. 21.* This is a large fruit, rounder than the Nivette, the skin is firm and adheres to the flesh, like the Nivette, but is of a deeper green; it is of a bright red towards the sun, marbled with deeper red, and the whole skin is covered with a white down, which easily rubs off with the hand: the flesh is firm, juicy, white inclining to green, and turns yellow when ripe, with some very red veins

near the stone: the juice is vinous, rich, and high-flavoured. It is ripe the latter end of September.

33. TEIN DOU. *Tein Doux. Duham. n. 36. t. 27. Pom. Franc. 2. p. 356. t. 19. f. 22.* This is large and nearly round; the skin is thin, covered with a very light and fine down. On the side next the sun it is of a faint red; the flesh is firm and white, and has some veins of faint red near the stone: the juice is sugary and of a delicate flavour. It ripens the end of September or beginning of October.

34. TETON DE VENUS. *Duham. n. 32. t. 23. Pom. Franc. 2. p. 357. t. 20. f. 23.* This is a middle-sized fruit, somewhat longish, and takes its name from its shape: the skin is covered with a fine down: it has but little colour on the side next the sun, and is straw-coloured on the shaded side; the flesh is fine, melting, white; rose-coloured at the stone, and the juice sugary and very rich. It ripens about the latter end of September.

35. \* PORTUGAL. This is a very large round Peach, of a beautiful red towards the sun, and generally spotted: the flesh is firm, white pale red at the stone, which is small, and the juice rich and vinous. It ripens late in September.

36. LATE CHEVREUSE. *Pourprée. Duham. n. 20. t. 14.* This is a longish fruit, of a good size, moderately cleft, and has a nipple at the end; the skin is greenish near the wall, but of a very fine deep red next the sun, hence the name *Pourprée*. The flesh is white, except round the stone: the

juice is excellent and very agreeable. It ripens the beginning of October.

37. LATE PURPLE. *Pourprée Tardive. Duham. n. 13. t. 9. Pom. Franc. 2. p. 359. t. 22. f. 26.*

This fruit is large, round, sometimes a little flattened at the head; the skin is covered with a fine down, tinged with a dark red or purple colour next the sun, and pale straw-yellow on the other side: the flesh is white, very red at the stone, melting, and the juice sugary and rich. It ripens the beginning of October.

38. YELLOW ADMIRABLE. *Pêche Abricotée. Orange Peach. Duham. n. 30. t. 22. Pom.*

*Franc. 2. p. 362. t. 24. f. 29.* This is a large excellent peach, round, slightly cleft. The skin is of a bright smooth yellow colour, covered with a fine down; it has a little red towards the sun; the flesh is yellow, of an Apricot colour, except near the stone, and under the skin on the sunny side, where it is red. It is firm, sometimes a little dry and woolly in cold autumns. The juice is agreeable with a little of the perfume of the Apricot in warm autumns. It ripens about the middle of October. It may be raised from the stone.

39. PERSIQUE. *Duham. n. 38. t. 29. Pom. Franc. 2. p. 360. t. 22. f. 27.*

This is a large oblong fruit, and has small knots or warts on it; at the stalk there is a remarkable one like an excrescence: the skin is of a pale yellow colour, with deep red next the sun; the flesh is firm yet juicy; white, and bright red round the stone. The juice

is high-flavoured, fine, very agreeable, and sometimes a little sharpish. It makes a fine tree, and bears well. It ripens the beginning of October. It may be raised from the stone. This has been frequently confounded with the Nivette.

40. \* MONSTROUS PAVY OF POMPONNE. *Royal Pavy. Duham. n. 35. t. 26. Pom. Franc. 2. p. 361. t. 23. f. 28.* This peach is round and of an extraordinary size, slightly cleft; it has a thin skin covered with a very fine down; of a fine red colour towards the sun, and pale greenish yellow on the shaded side; the flesh is firm, white, except near the stone and under the skin, where it is deep red; it is hard, yet juicy, and when the autumns are warm and dry the juice is vinous, musky, and very agreeable, but when the autumns are cold and wet it is insipid. It ripens the latter end of October.

41. SANGUINOLE. *Bloody Peach. Druselle. Duham. n. 41. Pom. Franc. 2. p. 362. t. 25. f. 31.* This is small and nearly round, the skin is of a deep dull red all over, and much covered with a ruddy down: the flesh also is deep red, like the beet-root, and somewhat dry: the juice is sharp and bitter, unless the autumn be warm. It seldom ripens in England without forcing, but is rich and excellent for baking and preserving.

42. \* CATHERINE. *Langley Pom. t. 33. f. 6.* This is a fine large fruit, of a round make, and of a beautiful red colour towards the sun; and white on the other side; the flesh is firm, white, deep red at the stone, and full of a rich juice; the

pulp is improved by its lying three or four days before it is eaten. It ripens about the latter end of October; but there are not many situations where it ripens well. It is a plentiful bearer. \*

43. **QUEEN CHARLOTTE.** This nearly resembles the Small Mignonne, and ripens about the same time.

44. **LOCKYER'S.** This is a fine handsome fruit, and ripens in September.

\* This is an excellent Peach for forcing, and will be highly acceptable to those who are fond of such as adhere to the stone; and as it is of a beautiful colour, it will make a very handsome appearance at table. Or, this fruit might have part of a wall appropriated to itself, and have the lights of the Peach-houses (after forcing is over), or Melon-lights, fixed upon a temporary frame against the wall. This would greatly forward the ripening of the fruit in bad seasons; and, as the tree is a good bearer, it would amply recompence any one for the trouble, by furnishing a supply of fruit for the table till the middle of November. This would also assist in ripening the wood well for the succeeding year.

This Peach is excellent for tarts.

*Of the Planting, Pruning, Training, &c. of Peach-Trees.*

Peaches require a lighter soil than Pears and Plums ; and a light mellow loam is best. If the natural ground should be a strong brick mould, or rather inclinable to clay, it will be necessary to take out some of it, particularly when you first make the borders, and mix with it some light mould, sand, or old lime rubbish. At first making the borders, you should take out the earth where the trees are to be planted, as before directed for Apricots : and keep working the rest with rotten leaves, or street-dung, and the above mixture ;

throwing them up, as early as you can spare them, in ridges rough from the spade, which will let the frost and sun penetrate and meliorate the ground.

If the ground should be wet, make some drains across the borders, to lead the water from the roots of the trees to a drain made along the middle walk. If the ground should have a slope, you can very easily convey the water off when the springs are near the surface; but if the wet be occasioned by rains, and the stiffness of the ground holds the water, you should give the border a proper slope to carry it off from the roots of the trees. Fill the cross drains, leading to that along the middle of the walk, with old bricks or stones at bottom, and at top with rough gravel \*, which will keep the ground dry; at the same time laying it sloping from the wall, so as to throw the water that falls in heavy rains towards the middle walk, where it will soon soak into the ground. When water is suffered to stand about the roots of tender trees in strong land, it is sure to bring on the mildew, which will spoil and render them good for nothing but the faggot-pile. Sometimes, indeed, I have recovered them, by moving them to another aspect. All the French Peaches are very liable to mildew on strong land.

\* The drains should be deep enough to have two feet of mould above the gravel; which will prevent their being hurt in trenching the ground.

Where there is not a proper descent to carry off the water, the bottom of the main walk should be filled up with brick-bats or stones, and the small stones raked from the quarters of the garden, making a dry drain along the middle, nine inches wide, or more, covered with bricks or stones. The walk, when finished, should have a gentle rise in the middle, in order to throw the rain-water toward the edges.

Where the soil is a sour wet clay, it will be necessary to throw into the bottom of the border brick-bats covered with lime-rubbish, or core from the screenings of lime; then water it, and when nearly dry ram it well, which will convert it into a hard solid surface, and prevent the roots of the trees from penetrating the wet earth below. It will also serve to carry off the water to the drains.

With regard to the choice of Peach-trees, the directions already given for Apricots will serve. They should be procured in the latter end of October, or beginning of November, as soon as the leaf begins to fall; and, if possible, the ground be ready before-hand.

The earlier you go to the nursery the better, to mark and take up the young trees; for he that goes first has the greater choice.

The ground, if new borders, should be well trenched to receive the trees; if to supply the places of others which have been removed, or where trees have died, all the old roots should be

carefully taken out, and fresh mould put in where the old was taken away; remembering to raise the new mould a proper height above the old; as it is a very great hurt to fruit-trees, when they are planted too deep: if they are not kept up above the level of the old ground at first, they seldom thrive well. When the trees are planted, water the roots well to settle the mould, letting it remain for some days, till the water is absorbed; then tread the mould, and fill the holes up to the top; observing the same rules as hereafter given in case of dry weather, letting your fresh-planted trees remain unpruned till the Spring.

When you see the buds begin to shoot, if the trees be maiden trees of one year's growth, you may head them to five or more eyes, according to their strength; then rub on a little of the Composition where you cut off the top, observing to cut it sloping, as before directed, and as near the top buds as may be, and also to rub off the fore-right shoots. When the young shoots have strength, nail them to the wall, to prevent their being broken by the wind. If the leading shoot be very strong, pinch off the top of it about the beginning of June, which will make it throw out some fine strong shoots, to help to fill the wall. None of the shoots should be suffered to grow too long during the first and second years; which may always be prevented by pinching the ends of them; but they should never be topped, when the tree sends out fine kind shoots, till the Spring following, when

you may prune them according to the strength of the tree, and the quantity of wood it has made during the preceding Summer, leaving your shoots from six to twelve inches long; by which means you will soon be able to fill the lower part of the wall. It is too common a practice to lay in the shoots at full length, taking off only the points of the branches, which generally, after a few years, leaves the walls quite naked: whereas, if attention were paid to the training, especially, for the first four years, you could always fill the walls with fine bearing wood from top to bottom, and the trees could produce a great deal more fruit, and of much finer quality, than when they are run up in the former way: for those trees, in general, are so weak that they have not strength to bear good fruit. The third year, if care be taken to manage the trees properly in Summer, you may bring them into a bearing state. If the ground be strong, they will grow very vigorously; in that case, you must pinch all the strong shoots about the month of June, which will make them throw out side-shoots; these, if not laid-in too thick, will make fine bearing wood for the succeeding year. If you suffer the strong shoots to grow to their full length, they will be large and spongy, and will neither produce fruit nor good wood for the following year. Weak shoots should never be nailed, although they may be full of blossom, as they never bear good fruit. Sometimes weakly trees are covered over with blossom; but if too much fruit be

suffered to remain on them, they will be weakened so much that they never will recover. In that case, I would recommend picking off the greater part of the fruit, to let the tree recover its strength. When you prune trees in the above state, observe never to prune at a single flower-bud ; if you do, you will be sure to kill the shoot ; or, at least, it will die as far as the next wood-bud. [See PLATE III. *fig. 2.*]

On observing, you will find some shoots, and sometimes whole trees, with nothing but single flower-buds. These sorts of shoots should be laid-in at full length. Always observe the next branch that has got some wood-buds, and cut it close, that it may produce fine wood to supply the place of those that have only flower-buds, which may be cut out next year.

When Peaches come into a bearing state, you will, in general, see two flower-buds close together ; if you look between these flower-buds, you will see what is called a wood-bud ; you should always cut at such double buds ; as from between them come out the shoots that produce the fruit for next year.

If you observe the above rules, you cannot mistake in pruning {your Peaches. [See PLATE III. *fig. 2.*]

When the trees come into a bearing state, you may keep them in a flourishing one by proper management, and attention to the Summer pruning. I have often topped the strong shoots twice in the

course of the Summer, before I could get them to produce fine kind bearing wood. I have often had shoots that grew, in the course of one Summer, upwards of six feet in length, and as thick as my thumb. When such shoots as these are laid-in near their full length, the lower part of the wall will be left naked [*See the PLATE, fig. 1.*]; besides, these strong shoots exhaust the tree of its strength, and never produce good wood when you neglect to top them in Summer. I would recommend to cut out such shoots when the trees are pruned in the Spring, and to leave only the fine kind bearing wood; (which you may know by two small leaves where the flower-buds will be in the following year; the strong shoots have only one leaf-bud at each eye;) always remembering to lay the branches as *horizontally* as you can, which will check the growth of the shoot, and make the wood much finer, and fit for bearing the succeeding year. You should always rub off all the useless side-shoots that cannot be nailed in against the wall, leaving only the best, and laying them in about three inches apart. Be very particular to pick off all the side-shoots that come out near the tops of the branches; which, if left, would weaken the fruit-bearing branches for next year. This should be done as soon as you can lay hold of these shoots with your finger and thumb: if you suffer them to grow strong, they will hurt the fruit-bearing shoot.

*Of Pruning, Training, and Nailing old Peach-Trees.*

When the trees run up to the top of the wall, leaving about three-fourths of it naked, [See PLATE III, *fig.* 3.] the best way is to cut them as far back as you can find any young shoots or buds. You must always leave some young shoots or buds on Peach-trees, otherwise you endanger the life of them. Never head them as you would Apricot, Apple, or Pear-trees. If you cut or head down Peach-trees without attending to the caution given above, you run a great risk of killing them; but if there are a few young shoots, the top may with safety be cut off, just above them, as they will lead the sap up and produce strong branches, which should be topped as you would do a young tree to fill the wall.

It is more difficult to procure new wood from old Peach-trees than from any other, except Nectarines. I have often made incisions in the old branches, about the joint, cutting out a piece from one to three inches, according to the size of the branches. [See PLATE XI. *fig.* 2.] This should be done in several places of the tree, to furnish it with young wood; always rounding the edges where the incision is made, which should be above the joint, and as near to it as may be. The operation should be performed in the month of April; but never cut off the old branches, unless you perceive some young shoots making their appearance. When they are about three or four inches

long, cut off the old branch, which will cause the fresh young wood to make a rapid progress the first Summer, and you will have fine fruit on them the following year.

Always use the Composition where you cut off old branches ; observing to round the edges and cut out the canker which you find in the old bark where the branch was amputated.

In Peaches, the canker is of a brown colour ; and, in the bark, it appears in small specks or dots, as if made with a pen. All these should be cut out clean ; for if any part of the canker remain, it will affect the new wood as it begins to grow. Wherever you see the gum oozing, you may be certain that the canker is not quite eradicated. — See the Chapter on the CANKER.

In the latter end of April it will be necessary to look over your trees, and rub off what superfluous foreright shoots remained after going over them the first time. Indeed, if you were to examine the trees once every fortnight it would be so much the better, as by so doing they can be kept in perfect order. I have so accustomed myself to look over my trees, that I do it as I walk about my ordinary business, which saves a great deal of time. Care should be taken not to let the shoots get too long before they are tacked to the wall, lest they should be broken by the wind. I do not however approve of nailing the young wood too soon ; for, by so doing, the heat of the sun will occasion them to grow too fast.

You may save some of the largest and straightest of the shoots that are cut off, and run them in \* among the small branches of the trees to prevent them from being broken by the wind. This will save a great deal of summer-nailing: I mean this for the second summer-nailing. At the time you do this, carefully take off all the side-shoots that come out from the tops of the young branches.

When the second nailing is done, if you should find any very strong shoots, they should be cut out, leaving the fine kind side-shoots that have been produced since the first topping; but only those that will bear fruit. If the Autumn should prove fine, the trees will continue in full leaf to the end of October, and sometimes to the end of November.

When the leaves begin to fall, take a soft broom, and brush it gently over the branches of the trees, in order to take off as many of the leaves as you can, without hurting the buds. Remember, however, to brush upward; for if you brush downward you will be very liable to break the buds.

As soon as all the leaves are off, I would advise to unnailed the young branches that were nailed in during the Summer, leaving the strong ones to

\* That is, let the middle of the branch run in, be on the outside of the shoot that you wish to preserve, and the ends tucked under the two adjoining branches. After the fall of the leaf it will be necessary to take out these loose branches; which will give the shoots more liberty, and admit the sun and air to ripen the wood before the spring pruning.

keep the tree fast to the wall. By these means, the branches, being loose from the wall, will receive the benefit of the sun and air, to ripen and harden the young wood, which will not then be so liable to be killed by a hard winter. Leaving the trees so till the Spring, when you begin to prune them, there will be great choice of fine bearing wood to fill the walls.

The nails and shreds that were laid up in Autumn; when the branches were unnailed, should be pointed and picked during the wet weather in Winter: they will then be fit to use again. The shreds that have been used in Summer should be soaked in boiling-hot soap-suds for three or four days, which will kill the eggs of earwigs and other insects, so very destructive to Peaches.

After the trees are cut and nailed, if the weather should be frosty, it will be necessary to cover them when the flowers begin to open. Some cover the trees with yew, and others with branches of fir, laurel, &c., but old netting is the best covering; and it should be put on three-fold, as directed for Apricots. When the leaves begin to cover the fruit, and the weather is likely to be fine and settled, the netting should be taken off by degrees, but by no means all at once. By the forked sticks, as before observed, the nets may be kept at what distance you please; but never be in too great haste to uncover the trees, nor suffer the shoots to grow through the meshes of the nets; for, when that is the case, a great many of them will be broken in

taking off the nets. The trees should be uncovered in cloudy weather, or when it is likely to rain ; if the nets be taken off in clear weather, the leaves are liable to be hurt by the sun. Be careful in taking off the foreright and side-shoots, not to expose the fruit ; rub them off near the extremities, leaving those which you want to fill up the wall as low on the branch as possible, at the same time leaving only one for a leading shoot. When the fruit is about the size of a small marble, begin to thin them : which operation must be left to the judgment of the person who does it ; but it should be according to the strength of the tree. This ought to be done very regularly, that the fruit may be equally dispersed over the tree. If left too thick, it will not have room to swell : this frequently happens. If the tree be very strong, you may leave from three to six Peaches on each shoot ; according to the strength and length of the branch.

I have observed, that where the Composition was applied to prevent the sap from being exhaled by the sun and air, all the trees that were very much loaded with fruit were not in the least hurt ; while the trees that were treated in the common way were greatly injured, and often killed, when they have had a great crop.

In very dry seasons, it will be necessary to make a large basin round each tree, or, rather, make up an edge around the whole border with mould, as you would for a bed to bed out plants in a nursery ;

I have often heard of Peaches and Nectarines growing on the same tree, but never had ocular demonstration till Mr. Wilmot, market-gardener near Smallbury Green, in the parish of Isleworth, last season sent me a Peach which partook of the nature of the Peach and Nectarine both in appearance and taste; and, he assures me, that several trees in his garden have for some years past produced fruit of the same kind. I also saw a Galande Peach-tree, last season, in Mr. Gilpin's garden at East-Shene, which had on one of its branches two Nectarines and a Peach. These I examined very minutely; and Mr. Gilpin had the goodness to send me one of the fruit, which had the appearance and flavour of a Red Roman Nectarine. There were Nectarine-trees of that kind on the same wall at no great distance. The only reason that I can assign for such phænomena is, that the farina might have been injured by the frost, or perhaps, in the former case at least, the farina of the Nectarine and Peach might have been intermixed, either by the wind or by bees. See "*Trans. of Hort. Soc. of London*," v. i. p. 103.

## CHAPTER IV.

## OF NECTARINES.

*A Description of Nectarines cultivated in England, and the Method of Planting, Pruning, and Training them.*

THE Nectarine (properly so called from Nectar, the poetical drink of the Gods,) belongs to the twelfth class of Linnæus; Icosandria Monogynia; and is named *Amygdalus Persica, Var. β. Nectarine*. It was cultivated here in the year 1562; according to Turner's Herbal. *Part 2. fol. 48. verso.*

This fruit differs from the Peach in nothing more than in having a smooth rind, and the flesh being firmer. \*

*The Varieties which are cultivated in this Country are,*

1. FAIRCHILD'S EARLY. This is one of the earliest: it is a small round fruit, of a beautiful red colour next the sun, and yellow on the other side. It is not very juicy, but is well-flavoured; and is ripe about the middle of August.

\* Those marked with an asterisk adhere to the stone.

2 \* LATE NEWINGTON. *Langley Pom. t. 29. f. 1.* This is a large fine fruit, of a beautiful red colour next the sun, and a fine yellow on the other side; the flesh is yellow, but deep red next the stone. It has an excellent rich juice, and ripens about the middle of September.

3. ELRUGE. *Clermont. Langley Pom. t. 29. f. 3. Hooker Pom. Lond. t. 1.* This is said to have been first cultivated by Gurle, a Nurseryman at Hoxton, in the time of Charles the Second. It is of a middle size, of a dark red or purple next the sun, and of a pale yellow or green on the other side. It has a soft melting flesh, very white, tinged with red next the stone, and vinous juice, and is ripe in the latter end of August, or beginning of September.

4. SCARLET. This is a middle-sized fruit, of a fine scarlet colour next the sun, but of a pale red next the wall. It ripens in the latter end of August, or beginning of September.

5. \* BRUGNON. *Italian. Langley Pom. t. 29. f. 4.* This is of a deep red next the sun, and of a pale yellow on the other side; the flesh is firm, very red at the stone; it has a rich flavour in a good year, and ripens in the latter end of August, or beginning of September.

6. \* RED ROMAN. *Brugnon Musqué. Duham. n. 26. tab. 18. Pom. Franc. 2. p. 353. t. 17. f. 18.* This is a large fruit, of a round shape; the skin dark red colour next the sun, but of a yellow colour on the other side; the flesh is whitish-yellow,

firm, and very red at the stone, and when full ripe it shrivels; the pulp is then replete with a rich juice. It is ripe in September. This Nectarine has a smooth leaf, and the Newington a jagged one: which is one of the most essential differences by which these two excellent fruits are distinguishable from each other.

7. \* MURRY. This is a middle-sized, roundish fruit, of a dull red colour towards the sun, and of a yellowish-green towards the wall. This fruit has a tolerably good flavour, and ripens about the middle of September.

8. TEMPLE'S. *Langley Pom. t. 30. f. 1.* This is of a middle-size, longish, of a pale red colour towards the sun, and of a yellowish-green cast next the wall; the flesh is white towards the stone. This fruit, when quite ripe, shrivels; the pulp is then full of rich juice of a fine flavour. It ripens about the middle of September, or beginning of October.

9. \* GOLDEN. *Langley Pom. t. 29. f. 5.* This is a middle-sized, round, handsome fruit, of a soft red colour towards the sun, and fine yellow on the other side; the flesh is yellow, and pale red at the stone. It has a rich flavour, and is ripe about the beginning of October.

10. PETERBOROUGH. *Late Green. Vermash.* This is of a middle size, round shape, and always of a green colour; the part next the sun is of the deepest green, the other side being paler; the flesh

is firm, and, in a good season, tolerably well-flavoured. It ripens about the middle of October.

11. VERMASH, TRUE. *Hooker Pom. Lond. t. 29.* This is a small round fruit, tapering towards the eye, of a very deep red colour next the sun, and greenish on the other side; the flesh is white, with a fine red circle next the stone, melting, and of a rich juicy flavour, relieved by an agreeable acid; stone small, parting from the flesh. It ripens the end of August, or beginning of September.

12. VIOLET. *Violette Hâtive. Duham. n. 23. t. 16. f. 1. Pom. Franc. 2. p. 347. t. 14. f. 15. Hooker Pom. Lond. t. 15.* This is of a middle size, oval shape, of a dark purple colour, sometimes a little mixt with scarlet next the sun, but pale-yellow on the other side; the flesh is white, inclining to yellowish-green, with a reddish circle round the stone. It has a fine flavour, sweet, and juicy; the stone is small, and parts from the flesh; and ripens in the latter end of August, or beginning of September.

13. WHITE. *Flanders. Pom. Franc. 2. p. 354. t. 18. f. 19.?* *Hooker Pom. Lond. tab. 30.* This is a middle-sized fruit, nearly round, and deeply cleft; the skin is of a pale-yellowish or cream colour, slightly tinged with red, with a few deeper coloured spots next the sun. The flesh is white to the stone, and of a rich juicy vinous flavour; the stone is small, and parts from the flesh. It ripens in August and September.

*Of the Management of Nectarines.*

It is unnecessary to say much on this head, as the management of Nectarines is almost the same as that of Peaches.

The same rules must be observed with regard to pruning and cutting-out diseased parts ; and the same attention will be necessary during the summer ; observing, in particular, not to lay-in the wood too thick.

On account of the smoothness of the skin of the Nectarine, it suffers much more from mille-pedes (or wood-lice), ear-wigs, &c. than the Peach ; it will, therefore, be necessary to hang up a greater number of bundles of bean-stalks about these than about any other fruit-trees. Wasps are also very destructive to Nectarines, and the trees are very liable to be infested with the red spider ; these are to be destroyed as hereafter directed.

Let the wall, with the stems and branches of the trees, be carefully inspected, and all the snails about them picked off and destroyed. The young snails frequently commit great depredations on the leaves before the fruit is ripe. — [See the Chapter on INSECTS.]

It may, perhaps, be necessary to observe here,

that after the fall of the leaf the young shoots should be unnailed, in order to harden the wood ; and in hot weather form basins on the borders, and mulch them, as directed for Peaches.

The same mode of watering with the engine is also to be observed in dry hot weather.

Do not omit to thin the fruit when grown to a tolerable size ; but never pick off the leaves till the fruit be full grown ; observing the rules already laid down for Peaches. It will answer equally well with Nectarines as with Peaches, to plant some trees on an East wall, which will continue the succession much longer than if all were planted in the usual aspects.

In the Summer of 1800, which was dry and hot, we had a West aspect which was so much infested with the red spider, that I expected the trees would have been totally destroyed. In February following, I had the wall well washed with soap and urine mixed, as also the stems and branches of the trees. (This must be done before the buds begin to open, and in the fore-part of the day, that the trees may get dry before the evening ; but never in frosty weather.) Afterwards, wherever I saw any appearance of the spider, I watered the trees with clear lime-water, as directed in Chapters III. and XXVIII. These trees are now in a perfectly healthy state ; but in some gardens, where these precautions have been neglected, many of the trees are entirely killed.

## CHAPTER V.

## OF CHERRIES.

*Different Sorts ; and the Propagation, Planting, Pruning, and Training of them. — How to preserve them from Insects.*

THE cultivated Cherry is said to have come originally from Cerasus, a city of Pontus, from which Lucullus brought it, after the Mithridatic war, into Italy. They so generally pleased there, and were so easily propagated in all climates into which the Romans extended their arms, that, within the space of a hundred years, they grew common as far as the Rhine, and were introduced into Britain about Ann. Dom. 55. \*

The Cherry belongs to the twelfth class of Lin-

\* It is supposed by many that Cherries were first introduced into this country in the reign of Henry the Eighth ; but Lydgate, who wrote his poem called " Lick-penny," before the middle of the fifteenth century, or probably before the year 1415, mentions them in the following lines, as being commonly sold at that time by the hawkers in London streets :

*Hot pescode own began to cry,  
Straberys ryce, and Cherryes in the ryce.*

Ryce, rice, or ris, properly means a long branch ; and the word is still used in that sense in the West of England. — See Warton's *Hist. of Eng. Poetry*, vol. ii. p. 367.

næus's System ; Icosandria Monogynia ; and is named *Prunus Cerasus*.

*A short Description of the principal Cherries cultivated in England.*

1. EARLY, or, SMALL MAY. *Langley Pom. t. 17. f. 2.* This is the first ripe, and requires a good wall. It is a small round red Cherry, and has a quick pleasant juice. One or two trees of this kind may be sufficient for a large garden. It is ripe in June.

2. MAY DUKE. *Langley Pom. t. 17. f. 3. Pom. Franc. 2. p. 40. t. 30. f. 24. Poit. et Turp. Fr. t. 123. Hooker Pom. Lond. t. 28.* This comes in about the same time as the former, but is larger : it is an excellent Cherry, and bears well against a wall. The fruit grows mostly in clusters, large, roundish, flattened at both ends, sometimes broad heart shaped, of a very deep brownish red colour, approaching nearly to black ; when well ripened, the flesh is soft, juicy, tender, with a pleasant acid, stone small, readily parting from the flesh. Ripens in June.

3. HOLMAN'S DUKE. *Langley Pom. t. 17. f. 1.* The branches of this tree are more spreading and loose than the May Duke ; but the fruit is larger, better flavoured, and comes into eating about a fortnight or three weeks later. The tree is not so good a bearer, neither does it succeed so well when forced.

4. ARCHDUKE. *Griottier de Portugal. Duham. n. 18. t. 13.? Pom. Franc. 2. p. 40. t. 27. f. 21.* This fruit is produced in clusters, like the May Duke, but is larger and finer to the eye; the taste is much the same, and comes into eating a fortnight or three weeks after. This, if permitted to ripen properly, is an excellent Cherry. It ripens the beginning of July.

5. LATE DUKE. *Royale. Chery-Duke. Duham. n. 20. t. 15.? Pom. Franc. 2. p. 40. t. 29. f. 23.?* This is a very good Cherry, and ripens after; the other Dukes. It is rather longer in shape than the May Duke, of a dark red colour, approaching to a black when the fruit is fully ripe. The flesh is red, firm, and very sweet.

6. KENTISH. *Montmorency à courte queue. Gros Gobet. Duham. n. 10. t. 8. Langley Pom. t. 18. f. 1. Pom. Franc. 2. p. 38. t. 22. f. 16. Poit. et Turp. Fr. t. 57. Pom. Aust. t. 18. f. 1.* This is a good Cherry, and a great bearer. It is of a bright red colour, and has an agreeable acidity. It ripens in July.

The fruit is large, very flat at both ends; stalk thick, strong, and sunk in a deep hollow; the skin of a lively and shining red, but not deep coloured; the flesh firm, white, a little yellowish; the juice plentiful, very agreeable, a little acid.

7. HERTFORDSHIRE. This is a sort of Heart, but firmer, and of a finer flavour than Hearts in general. It does not ripen till the latter end of

July or beginning of August, which renders it the more valuable, as it succeeds more early Cherries.

8. BLEEDING HEART. *Gascoign's. Langley Pom. t. 17. f. 4. and 5.* This is a very large Cherry, of a long form and a dark red colour: it has a pleasant taste, and ripens in the latter end of July.

9. HARRISON'S HEART. This is a fine Cherry. It was introduced from the East Indies by Governor Harrison,\* grandfather to the present Earl of Leicester, and first cultivated at his seat of Balls in Hertfordshire. Some of the trees, I am informed, he presented to George the First; and they are at this time in a flourishing state, bearing fine fruit, in Kensington Gardens. This Cherry is ripe in July and August.

10. BLACK HEART. *Langley Pom. t. 18. f. 5.* This is a fine Cherry, too well known to require description. The tree bears better than the other Hearts.

11. WHITE HEART. *Langley Pom. t. 18. f. 4.* This fruit is of a whitish-yellow colour, tinged with red next the sun; the flesh is juicy, and of a very rich flavour; the stone is large. It ripens in July and August.

12. MORELLO. *Milan. Langley Pom. t. 16. f. 2. Pom. Aust. t. 20. f. 1.?* This is a large round dark red coloured Cherry, turning almost black

\* Governor Harrison went out Governor of Fort Saint George in December 1710, and returned home in 1719; and it is probable he brought this Cherry with him: if so, some of these trees in Kensington Gardens must be upwards of eighty years old.

when well ripened; the flesh red, tender, juicy, blended with an agreeable acid. It is a very fine fruit, when kept till the month of October, and makes a very great addition to the dessert at that time of the year. This is the best Cherry that we have for preserving, and for making cherry-brandy.

13. CARNATION. *Langley Pom. t. 16. f. 3.* This takes its name from its colour, being red and white. It is a large round Cherry, with a firm fleshy fruit, but not so sweet as the Duke Cherry. It ripens the latter end of July.

14. LARGE SPANISH. This is nearly allied to the Duke Cherry, of which it appears to be only a variety. It ripens soon after the common May Duke, and very often passes for it.

15. YELLOW SPANISH. This is of an oval shape and amber colour. It is a sweet pleasant fruit, but not of a rich flavour. It ripens in August and September, but being an indifferent bearer is not much cultivated.

16. CORONE. *Coroun. Langley Pom. t. 16. f. 1.* This is a large roundish black Cherry, full of a sweet and rich juice. It is an excellent fruit and a good bearer. It ripens about the beginning of August.

17. LUKEWARD. This is a middle-sized fruit, of a dark brown or black colour. It is a fine pleasant fruit and a good bearer. It ripens in the beginning of August.

18. GRAFFION. *Cerise Ambrée. Duham. n. 14. t. 11.* This is supposed by many to be the same

with Harrison's Heart: but upon a close examination, I find it to be a different Cherry; the flesh is firmer, and the stone flatter. It ripens in July and August.

The *Cerise Ambrée* is thus described by Duhamel — This is a large Cherry, round at the head, but flattened at the other end; skin fine, a little thick; when exposed to the sun, of a bright red colour, and on the shaded side spotted or marbled with light red and yellow; when covered by the leaves it is of a yellow amber colour over the greater part, and the rest bright red, and before ripening it is amber all over. The flesh a little transparent white, sprinkled with whiter veins, and very slightly tinged with red under the skin next the sun; the juice plentiful, sugary, and very excellent, when fully ripe; stone white, with a very small sharp point. It ripens end of July and August.

19. BIGARREAU. *Hooker Pom. Lond. t. 46.* The Bigarreau Cherries of Duhamel, &c. are ranged in the class of *Heart-shaped* Cherries; but none of those described by him resemble this Cherry so called in the English Gardens, and which appears to be the Graffion, or Ambrée of Duhamel. See n. 18. It is a very large fruit, of an irregular obtuse heart-shaped form, flattened next the stalk; of a pale yellowish or amber tint on the shaded side, and of a fine red colour next the sun. The flesh is firm, white, slightly adhering to the stone, sweet and well-flavoured; stone large and round. It ripens in July or beginning of August.

20. RONALDS' LARGE BLACK HEART. *Black*

*Circassian.* *Hooker Pom. Lond. t. 31.* Introduced into this country in 1794, from Circassia. Mr. Ronalds, Nurseryman at Brentford, and the only person, to the best of my knowledge, who has cultivated it in England, sent me some of the fruit this summer, 1801. It is a fine large Cherry, and will, without doubt, be valuable as a forcing sort. This Cherry, in my opinion, is well worth cultivating. It ripens in the beginning of July. The fruit, usually produced in clusters like the May-Duke, is very large, heart-shaped, flat next the stalk, of a very deep red, or rather purplish colour, turning black when fully ripe; the flesh firm, and full of sweet rich juice, slightly aromatic; the stone is oval, small.

21. FRASER'S BLACK TARTARIAN \*. This is a fine large fruit.

22. FRASER'S WHITE TARTARIAN. This is white and transparent. These Cherries are excellent bearers, but particularly the black kind: the fruit is of a fine brisk flavour, and it ripens early.

\* The Tartarian Cherries were brought from Russia in the Autumn of the year 1796, by Mr. John Fraser of Sloane-square, Chelsea; well known for his indefatigable industry in collecting many curious plants, and other natural curiosities, in North America and the West Indies. He says, that these Cherries are natives of the Crimea, and that he purchased them of a German, who cultivated them in a garden near St. Petersburg. This man had but few plants of them at that time, and sold them as a favour at ten roubles a plant. Mr. Fraser afterwards saw them in the Imperial gardens, where they were successfully forced in pots.

23. LUNDIE GEAN. This sort, cultivated at Lord Viscount Duncan's, near Dundee, is black, and almost as large as a Black Heart Cherry. It is now common in the nurseries about Edinburgh; and Messrs. Gray and Wear have had it for some years in their nursery at Brompton Park.

24. TRANSPARENT GEAN. This is a small delicious fruit.

From the Black Cherry, which is supposed to be a native of England, are raised by seeds, the black Coroun, and the small wild Cherry, of which there are two or three varieties, differing in the size and colour of their fruit. I would recommend planting these in parks and pleasure-grounds, as the trees grow to a great size, and have a beautiful appearance. The fruit will be food for birds, and so be the means of preserving the finer fruit in the garden and orchard from their depredations. The wood also of these trees is very useful for turners and picture-frame makers. Stocks to graft upon are generally raised from the seed of this sort. These trees will thrive in poor land, where scarcely any other sorts will.

The Cluster Cherry. *Langley Pom. t. 18. f. 2.*  
*Pom. Franc. 2. p. 38. t. 20. Pom. Aust. t. 13.*  
 This is planted more for ornament, or curiosity, than for any other purpose.

*Planting, Pruning, and Training of Cherry-Trees.*

In the choosing and planting of young Cherry-trees, the same rules are to be observed as are given for Apricots, Peaches, and Nectarines; and they must in like manner be headed down the first year.

In pruning Cherries, never shorten their shoots; for most of them produce their fruit at the extremities; the shortening, or cutting-off, of which very frequently occasions the death of the shoot, at least of a great part of it. The branches, therefore, should be trained at full length. I have often seen the whole tree killed by injudicious pruning. Wherever the knife is applied, it is sure to bring on the gum, and afterwards the canker, which will inevitably kill the tree if no remedy be applied to the wounds.

I have headed down a great many Cherry-trees which were almost past bearing, and so eaten up with the gum and canker, that what few Cherries they bore upon old cankered spurs were not fit to be sent to the table.

In the years 1790 and 1791, I cut, or headed down, fifty trees. The operation was performed in the months of April and May in each year. These trees made shoots from three to five feet

the same summer, bore fine Cherries the next year, and have continued to bear good crops ever since.

To the above trees I applied the Composition. At the same time I cut down twelve trees in the same row, but did not apply the Composition : these twelve trees all died in the second and third years after. We now gather more Cherries from one tree where the Composition was applied, than we did from the whole number formerly ; being also much finer and larger fruit.

When Cherry-trees are very old, and much injured by large limbs having been cut off (which will infallibly bring on the canker and gum, and if no remedy be applied, in a short time kill the trees) ; or if there are great spurs left standing a foot perhaps from the wall (*See PLATE IV. Fig. 2.*) ; the best way to bring them to have fine heads, and to cover the wall, is to head them down as low as possible, taking care to leave some small shoots, if there are any ; if not, leave a bud or two at the ends of some of the shoots. Sometimes you will have a great difficulty to find any buds. If that be the case, in the Spring, before you mean to head the trees, make some incisions in the branches. (*See PLATE XI.*) This should be done on different branches, at the most convenient places for filling the wall with good wood. The size of the incisions should be from one to two inches, according to the largeness of the branches ; observing to make them just above the joint where the

buds should come out. If you cut just below a joint, the shoot will die as far as the next bud or joint; and, of course, injure the tree, if no remedy be applied.

The time for performing this operation is in March, April, or May. The above method of making incisions is only recommended, where there are no young shoots or buds, and when the tree is in the last stage of the canker.

Where you have a few young shoots, or buds, cut down the head as near to them as you can, and take great care to cut out the canker till you come to the sound bark. The canker makes its appearance in Cherry-trees in the same manner as it does in Peach and Nectarine trees, and may be easily discovered by an attentive observer. If any gum remains, it must be cut or scraped off; the best time for doing this is when it is moistened with rain; you can then scrape it off easily without bruising the bark. This operation is very necessary; and if it be neglected the disease will increase rapidly.

Wherever the bark or branches have been cut off, the edges should be rounded, and the Composition applied.

The general way of pruning Cherry-trees has been to leave great spurs, which continue to increase till they stand upwards of a foot from the wall, and become as thick as a man's arm; but be it observed, that cutting off, from year to year, the shoots that are produced from the spurs, increases

the canker, till large protuberances, like wens, are formed on the branches, becoming very unsightly ; and these occasion them to produce only small and ill-flavoured fruit, at a great distance from each other. (*See PLATE IV. fig. 2.*) When this is the case, the method I pursue is, to head the trees down as before directed.

If the young shoots are properly trained, they will produce fruit the following year ; and in the second year they will produce more and finer fruit than a young tree that has been planted ten or twelve years.

It has been a general complaint, that Heart Cherries are bad bearers when trained up as wall-trees ; but, by pruning them as Duke Cherries, I have brought them to bear in the same manner ; that is, I leave a great many fore-right shoots in Summer, and tuck them in with some small rods run across under the adjoining branches, to keep them close to the wall, and prevent them from being broken by the wind, and from looking unsightly.

Never make use of the knife in Summer \*, if it

\* As Morello Cherries bear their fruit on the second year's wood, from two to five in a cluster, and not on spurs as other cherries do, the strongest and cleanest wood should be laid in at full length in the Summer, and all superfluous shoots be rubbed off, leaving a regular supply to fill up the walls. They should be pruned and nailed at the same time with other Cherries, either in Autumn or in the month of March ; but we prefer Spring pruning.

be possible to avoid it, as the shoots die from the place where they are cut, leaving ugly dead stubs, which will infallibly bring on the canker. These shoots may be cut in the Spring to about a couple of eyes, as Duke Cherries, which will form a number of flower-buds, as appears in PLATE IV. *Fig. 1.* — *Fig. 2.* is an old branch, to show the manner in which the spurs are formed when the old method of pruning is followed, and the barren unproductive state of the tree.

As Cherries are a very considerable article of traffic in the London markets, and the markets of most towns throughout the kingdom, employing such a great number of people during the Summer season in gathering, carrying to market, and selling them, the raising of them is certainly worth any gentleman's while, especially as the trees may be rendered ornamental as well as profitable, by planting them in shrubberies, &c. \* Gentlemen of small fortune, who are at a great expence with their gardens and plantations, may in a great measure re-imburse themselves by selling their Cherries and other fruit (for which there will be plenty of chapmen), and thus enjoy at an

\* At Ashted park, the seat of Richard Bagot Howard, Esq. near Epsom, there is a Cherry-tree between fifty and sixty feet high ; and at four feet from the ground, nine feet six inches in circumference. This tree, with many others of the same kind, was planted several years after the Chesnuts mentioned in Chap. XX.

easy rate the pleasures of a rational and useful recreation.

In all parts of the country there are persons employed in collecting fruit for the markets, and to hawk it about from place to place ; and surely it is much better to sell it to them, than to let it rot on the ground, or be devoured by birds and insects.

When Cherry trees begin to produce spurs, cut out every other shoot to make the tree throw out fresh wood ; when that comes into a bearing state, which will be in the following year, cut out the old branches that remain ; by that method you will be able to keep the trees in a constant state of bearing, taking the same method as before directed with the fore-right shoots.

Great care should be taken to rub off many of them in the month of May, leaving only such a number as you think will fill the tree. By so doing your trees will continue in a fine healthy state, and not be in the least weakened by bearing a plentiful crop of fruit. The reason is obvious : the great exhalation which would be occasioned by the sun and air in the common mode of pruning is prevented, by the Composition keeping in the sap which nourishes the branches and fruit.

I cut some trees, as directed above, more than twelve years ago, that are now in as good a state of bearing as they were in the third year after the

operation, and likely to continue so for many years.

In 1797, I pruned some very old trees in the month of May, which were left, to show the old method of pruning; I, at the same time, cut some branches of the same trees according to the new method, to show the difference of the fruit, which was taken by all who saw it for a different sort of Cherry. The Cherries from the old spurs were not half the size of the others, and were at least three weeks later.

I am sorry to say, that many who have seen the improved state of the fruit trees in Kensington Gardens still have their own managed according to the old method of pruning. Several, however, have adopted the new method with great success. One gentleman in this neighbourhood, by renovating thirty-nine old Morellos planted on a North wall 176 yards long, and ten feet high, was in a few years able to sell yearly, on an average, from thirty to forty pounds worth of fruit produced from them, besides supplying his own family. In some years the Market-Gardener who sold them allowed him three shillings per pound weight.

A row of Dwarf Cherry-trees that stood against an old paling in Kensington Gardens, with an old thorn hedge at the back of it, (which every year so infected them with a blight, accompanied by an immense number of caterpillars and other insects, that even in a fine year we could not gather eight

baskets from the whole row,) became so fruitful after the hedge and paling were removed, that we gathered forty-two pounds a-day for six successive weeks, besides what the birds, wasps and flies destroyed.

This estimate is within the bounds of truth ; and I mention the fact to stimulate Market-Gardeners and Farmers, who have large orchards and gardens, to exert themselves in trying every method, however unimportant it may at first appear, to improve and render them more fruitful.

The Duke and Heart Cherries from these trees were as fine as any that were produced from wall trees ; and, as they are much more productive, I have been induced to take up many of the old renovated trees from the walls, and plant them out for dwarf standards, supplying their places with Pears, Plums, Peaches, &c.

In all old gardens and orchards throughout the kingdom, and particularly in Kent, whence the London markets are chiefly supplied with Apples and Cherries, the greater part of the old trees will hardly bear fruit sufficient to pay the expence of gathering it ; but if the above method of pruning, &c. were practised, the owner would soon find his account in it, and be amply repaid for his trouble. The fruit would be much finer, and he would have five times the quantity that the trees produce in their present condition ; the trees would be more sightly, and always keep in a flourishing and bearing state.

When old standard Cherry trees become decayed and hollow, I would recommend heading them down, as directed for wall-trees and dwarfs. Scoop out all the rotten, loose, and decayed parts of the trunk, till you come to the solid wood, leaving the surface smooth ; then use the Composition as hereafter directed.

## CHAP. VI.

## OF APPLES.

*Different Sorts of Apples described. — Of Heading Apple-Trees. — Of Espaliers and Dwarfs. — Grafting old Apple-Trees ; and of the Advantage of using the Composition in that Operation.*

LINNÆUS has joined the Pear, the Apple, and the Quince together, making them all of the same genus, and has reduced all the varieties of each to one species. They belong to his Twelfth Class, Icosandria Pentagynia. The Apple is named *Pyrus Malus*.

The species are,

1. THE WILD APPLE, with a very sour fruit commonly called Crab.

2. WILD CRAB OF VIRGINIA, with a sweet-scented flower.

3. THE DWARF APPLE, which is rather a shrub than a tree ; commonly called Paradise Apple.

*The following are the Sorts of Apples which are most esteemed in England.*

1. ACKLAM'S, or ACLEMY RUSSET. This is a small Yorkshire Apple, of a russet colour towards

the sun, and yellow on the other side ; it is ripe in January, and keeps till March.

2. AROMATIC PIPPIN. This is a very good apple, of a bright russet next the sun ; and the flesh has a fine aromatic flavour. It ripens in October.

3. BAXTER'S PEARMMAIN. This is a real Norfolk apple, of a handsome size, and pale green colour, full of small dark spots. A fine kitchen fruit, and will keep till April. This is also a good eating apple.

4. BEAUTY OF KENT. This is a fine large apple, resembling a Codlin. It is streaked with a fine red towards the sun, and of a beautiful yellow, with some streaks of red on the other side. This is a very good apple, comes into eating in September, and keeps till the latter end of April.

5. BELLE GRISDELINE. This new seedling was raised at Norwich ; and struck all who saw it with its beauty and never-failing crops. Mr. Lindley \* first propagated it about seven years ago, and gave it the above name. The original tree died two years ago. This is a handsome apple, resembling the Borstorff, of a yellow colour, with red towards the sun. It is an excellent table apple, and will keep till March.

6. BELL'S PEARMMAIN. This is a real Norfolk apple : it is large and handsome ; red towards the sun, and yellow on the other side. It is a fine

\* Nurseryman near Norwich.

kitchen fruit, and pretty good to eat raw. This apple will keep till June.

7. **BEST POOL.** This is a middle-sized apple, of a pale green colour, streaked with red towards the sun. It is a good apple, and is in eating from January to April.

8. **BLACK APPLE.** This is a middle-sized fruit, of a dark mahogany colour next the sun, but fainter on the other side. It is of a pleasant sweet taste, and keeps till the middle of April.

9. **BLAND'S SUMMER PIPPIN.** This is a handsome apple, of a gold colour, and an agreeable flavour. It is a great bearer, ripe in September, and keeps till Christmas.

10. **BACHE'S fine small TABLE APPLE.** This is about the size of a small Golden Pippin; red towards the sun, and green on the other side. It has a sugary taste, and comes into eating in January.

11. **BOOMREY.** This is a pretty large handsome apple, of a flat shape, and deep red colour; and the flesh is streaked with red. This apple is not fit to eat raw, but will do well for cider, or for the kitchen. It keeps till April.

12. **BOVEY REDSTREAK.** This is a handsome apple, of a flattish shape, beautifully streaked with a bright red next the eye, which is small, and of a yellow colour about the footstalk. It keeps till the latter end of October.

13. **BREEDON PIPPIN.** *Hort. Soc. Tr. 3. p. 268. t. 10. f. 1.* This apple much resembles the Court-of-wick Pippin, though it is a superior fruit; but

is larger and broader, proportionably to its length. It is flatly conical; the eye placed in a broad shallow cavity among many plaits. The skin is of a deep dull yellow, tinged with reddish orange, inclining to redness next the sun; the flesh yellowish, firm, very sweet, with a rich vinous spicy acid. It ripens in October and November.

14. BROAD-EYED PIPPIN. This is a fine large flat apple, with a very large eye; the colour is a greenish-yellow, with a little red towards the sun. This is a good apple, and keeps till May.

15. BRANDY APPLE. This is about the size of a Golden Pippin, flat-shaped, and of a yellowish russet colour; it is of a pleasant flavour; comes into eating in January, and keeps till March.

16. BORSTORFF. *Postophe d'Hiver. Queen's Apple. Langley Pom. t. 77. f. 6. Knoop Pom. p. 35. tab. 10. Duham. n. 6.* This is a beautiful fruit, red next the sun, and of a fine yellow on the other side. This is a very fine apple; and in my opinion, next in perfection to the Golden Pippin, and about the same size. It is in eating from November to the end of March.

The Queen was so fond of this apple, that she had a considerable number of them annually imported from Germany.

17. CADBURY POUND. This is a middle-sized apple, of a light-green colour. This apple is of a good flavour; ripe in January, and keeps till March.

18. CALVILLE, SUMMER. *Passe Pomme-blanche.*

*Duham. n. 1. t. 1. Knoop Pom. p. 8. tab. 1.* This is a small conical fruit, with ribs; of a whitish colour, streaked with red; the flesh is dry, and has little flavour. It ripens in July, and is only valued for its earliness. There is also a red variety.

19. CALVILLE, AUTUMN RED. *Knoop Pom. p. 15. tab. 3.* This is a middle-sized fruit, of a conical shape, and a fine red colour next the sun; the flesh is a little tinged with red, of a vinous taste, and is much esteemed by the French.

20. CALVILLE, WINTER RED. *Duham. n. 4. t. 3. Knoop Pom. p. 39. t. 11.* This is a large ribbed fruit, with a deep red skin; the flesh also is often reddish nearly all over, and the juice firm and vinous. It will keep to the end of March.

21. CALVILLE, WINTER WHITE. *Duham. n. 3. t. 2. Knoop Pom. p. 41. t. 11.* This is a very large fruit, with uneven sides, of a pale yellow colour, inclining to green; the flesh is tender and juicy. It is in eating from December to April. The fruit is nearly oval, broad and flat next the stalk, the eye is open, slightly hollowed, and surrounded by a few plaits; it is of a greenish-yellow when on the tree, but when ripe is of a fine rich gold colour, tinged with red next the sun, and covered over with small brown dots. The flesh is yellow, rather firm, rich, and juicy.

22. CARNATION APPLE. This is a beautiful middle-sized fruit, finely striped with red. It is ripe in January, and keeps till May.

23. **CARBERRY PIPPIN.** This, in size and shape, resembles the French Crab, and is of a deep-green colour. It is a good baking apple, and will keep till March.

24. **CARAWAY RUSSET.** This is a handsome russet-coloured apple, and about the size of a Nonpareil.

25. **CAT'S HEAD.** This is a large oblong apple, of a greenish-yellow colour, with a little brownish-red next the sun ; sometimes the colour inclines to a russet. This is a good baking apple, and is in eating from October to December.

26. **COCKAGEE.** This is a conical-shaped middle-sized apple, red on that side next the sun, and of a fine yellow colour on the other. If properly managed, this fruit will keep till February. It is a famous cider apple, and bakes well.

27. **CODLIN.** *Langley Pom. t. 74. f. 3.* This is generally the first apple that is brought to market. This fruit is so well known that it needs no description. It is in eating from July to December ; and is good either for baking or boiling.

28. **CORNISH NONPAREIL.\*** This is rather under the middle size ; it is a little flatted, and of a russet colour. This is a very good apple, and keeps till the middle of March.

29. **CORNISH PEARMAN.** This is of a middling size, and long shape ; of a dull-green colour on one

\* This and the other Cornish apples were sent to me, from Penzance, by Mr. John Duncan.

side, and russet on the other. This is a very good apple, and keeps till the latter end of April.

30. COURT-OF-WICK PIPPIN. *Hooker Pom. Lond. t. 32.* This is thus described by Mr. Billingsley, in his “Survey of Somersetshire;” “The favourite apple, both as a table and cider fruit, is the Court-of-Wick Pippin; taking its name from the spot where it was first produced. It originated from the pip, or seed, of the Golden Pippin, and may be considered as a beautiful variety of that fruit. In shape, colour, and flavour, it has not its superior. The tree is large, handsome, and spreading, and a very luxuriant bearer. On the whole, it cannot be too strongly recommended. The fruit is nearly oval, broad and flat next the stalk; the eye is open, slightly hollowed, and surrounded by a few plaits: it is of a greenish-yellow when on the tree, but when ripe is of a fine rich gold colour, tinged with red next the sun, and covered over with small brown dots: the flesh is yellow, rather firm, rich, and juicy. It comes into eating in December and January.

31. COCKLES PIPPIN. This is a handsome oval-shaped apple, below the middle size, of a russet colour, mixed with yellow and red. It keeps till April.

32. COURT-PENDU. *Fenouillet rouge; Short-stalked Russet. Langley Pom. t. 75. f. 2. Duham. n. 11. t. 6. Poit. et Turp. Fr. t. 67.* This is a very large apple, of an oblong irregular shape, and has a red cast on the side towards the sun; but is pale-grey on the other side. The stalk is thick, and very short, whence the name of Court-pendu. It comes

into eating in September, and in some seasons will keep a long time.

33. DALMAHOY PIPPIN. This is about the size of a Golden Pippin, of a green colour, and a little streaked with red towards the sun. It has a tolerable good flavour, rather sharp; and is in eating from September to February.

34. DREDGE'S SEEDLING. This is a fine large apple, striped with red next the sun, and of a yellowish-green on the other side. This is an excellent kitchen apple, of a pleasant taste; and will keep till the latter end of January.

35. DREDGE'S BEAUTY OF WILTS. This is a beautiful apple, of a good size, and one of the finest yet known in point of general utility. It is of a fine bright yellow colour, spotted with red towards the sun; and has an excellent vinous flavour. This apple is good either for the table or baking; and will keep till March.

36. DREDGE'S RUSSET. This is a small apple, of a greenish-russet colour, and of a pleasant flavour. It is ripe in November, and keeps till Midsummer.

37. DREDGE'S WHITE LILY. This is a fine apple, of an exceeding high flavour; and will keep till March.

38. DREDGE'S FAIR MAID OF WISHFORD. This is a fine middle-sized apple, of a yellowish-green colour, with some russet next the sun, and of an excellent flavour. It is a great bearer, and is in eating from Christmas to Easter. This is an excellent dessert apple.

39. DREDGE'S QUEEN CHARLOTTE. This is a beautiful middle-sized apple, of a gold colour, with red towards the sun. This apple is of an exquisite flavour, comes into eating about Christmas, and keeps till February.

40. DREDGE'S FAME. This is a good-sized apple, red towards the sun, and streaked like the Ribston Pippin on the other side. This is a most excellent apple, and is in eating from Easter to Midsummer.

41. DUMPLING APPLE. This is a handsome apple, and rather above the middle size, flat-shaped, and of a greenish-yellow colour, with some faint streaks of red. It keeps till March.

42. DUTCH QUEENING. *Winter Queening*. This is a large apple, somewhat resembling the Cat's Head in shape. The colour is red next the sun, and green on the other side, with sometimes a little red. This fruit is fit only for the kitchen, and for making cider. It is ripe in January, and keeps till the end of March.

43. DYMMOCK RED. This is under the middle size, of a fine red colour, intermixed with a little yellow on the side from the sun. It is ripe in January, and keeps till March.

44. ELTON'S YELLOW KERNEL. This is a handsome middle-sized apple, of a yellow colour. This is a good table apple, and is in eating from January to March.

45. ENGLISH RENNET. *Knoop Pom. p. 26. t. 7.* This is a handsome apple, beautifully streaked

with red, but darkest towards the sun ; of a tolerable flavour, but apt to grow mealy when kept too long. It keeps till the middle of May.

46. EMBROIDERED APPLE. This is pretty large, and the stripes of red very broad, from which circumstance it takes its name. It is commonly used as a kitchen apple, and is ripe in October.

47. EVERLASTING STRIPED APPLE. This is below the middle size, of a conical shape. The colour is a striped green towards the foot-stalk, and red towards the eye.

48. FAMEUSE. *Pomme de Niège*. This is a pretty large apple, of a beautiful dark red, with a little yellow on the side from the sun. The flesh is very white, and full of a rich sugary juice ; and it comes into eating about the latter end of October. This apple was introduced from Canada, by Mr. Barclay, of Brompton, Middlesex.

49. FENOUILLET GRIS. *Anis. Duham. n. 10. t. 5. Poit. et Turp. Fr. t. 151. Langley Pom. t. 75. f. 1.* This is a middle-sized fruit, of a grey colour ; the pulp is tender, and has a spicy taste, like aniseed. It ripens in September and October.

50. FLOWER OF KENT. This is a large handsome apple, of a yellow colour, and pretty good flavour. It keeps till the middle of April.

51. FOX-WHELPS. *Pom. Heref. tab. 3.* This is a small apple, streaked with red. It is ripe in January. This is a cider apple.

52. FRANKLIN'S GOLDEN PIPPIN. This is a handsome middle-sized apple, of a conical shape,

and gold colour, and beautifully marked with dark spots. This fruit has a fine aromatic flavour, and deserves the first place on the table: but it is a shy bearer. It comes into eating about the middle of November.

53. FRENCH CRAB. This is a large handsome globular apple, of a deep-green colour, with a little red next the sun. This apple will keep all the year. It is a good baking apple, and, if the Summer be warm, pretty good eating. It is moreover a great bearer.

54. FRENCH CODLIN. This is a pretty large apple, of a conical shape, and of a green colour, with red towards the sun, and comes into eating in January.

55. FEARN'S PIPPIN. *Hooker Pom. Lond. t. 43.* This is of the shape and size of a Nonpareil. The fruit is rather large, of a compressed globular form, flattened at both ends. It is of a beautiful scarlet colour next the sun, and of a golden yellow on the other side, with some streaks of russet-brown around the stalk, and dotted all over; the eye is small, round, not deeply sunk, and with some small plaits round it; the flesh is greenish-white, firm, sweet, and well-flavoured. It makes a fine show at table; is ripe in December; and will keep till the latter end of February.

Last Spring I received a beautiful variety of this fruit from Mr. Dredge, of Wishford, near Salisbury.

56. FRENCH SPANIARD (from Enmore Castle).

This is a large apple, in form of a hexagonal prism, with the angles a little rounded, and of a yellowish-green colour; it is pretty good, and keeps till the latter end of April.

57. FRENCH RENNET. *White Rennet. Langley Pom. t. 76. f. 3. Knoop Pom. p. 33. tab. 9. Poit. et Turp. Fr. t. 49. Duham. n. 17.* This is a large round-shaped fruit, of a yellowish-green colour, with some grey spots. It has a sugary juice, and is good either for eating or baking. It is in eating January and February.

58. GARGEY PIPPIN. This is a handsome conical-shaped apple, under the middle size, of a greenish-yellow colour, with a little red towards the sun. This is a pretty good apple, and keeps till May.

59. GILLIFLOWER. This is a fine handsome apple, red towards the sun, and of a yellowish-green on the other side. It is of a fine flavour, and keeps till the latter end of March.

60. GOLDEN RENNET. *Duham. n. 15. Langley Pom. t. 74. f. 6. Knoop Pom. p. 35. tab. 10.* This is a beautiful apple, a little flattened; of a fine red colour towards the sun, and yellow on the other side. This is a good eating apple, and keeps till February.

61. GOLDEN RUSSET. *Aromatic Russet?* This is a fine middle-sized apple, of a golden-russet colour, from which it takes its name. This is a good apple, and keeps long.

62. GOLDEN PEARMAIN. This is a fine apple, above the middle size, of a fine deep red towards

the sun, with a little yellow on the other side : when much exposed to the sun, it is sometimes red all over.

63. GOLDEN MUNDI. *Pear Russet*. This is a fine handsome apple, beautifully streaked with red ; of a good flavour, excellent for baking, and will keep till January.

64. GOLDEN GLOUCESTER. This is a handsome middle-sized apple, of a flat shape, and gold colour, with red towards the sun. This is a good apple, and keeps till March.

65. GOLDEN KNOB (from Enmore Castle). This is a handsome, though rather small, apple, of a fine gold colour, sometimes inclining to a russet. This apple has a pleasant flavour.

66. GOLDEN PIPPIN. *Reinette d'Angleterre*. *Dukam. n. 14. tab. 7. Pom. Heref. tab. 2. Langley Pom. t. 74. f. 7. and t. 79. f. 5. Poit. et Turp. Fr. t. 53. Knoop Pom. p. 33. t. 9.* This is well known ; and the French own it to be of English origin. It is almost peculiar to England ; for there are few countries abroad where it succeeds well. It is yellow as gold ; the juice is very sweet ; the skin (especially where exposed to the sun) is often freckled with dark yellow spots. ' It is certainly the most antient, as well as the most excellent, apple that we have. It ripens in October, and will keep through the Winter. There are several varieties of this fruit.

67. GODOLPHIN APPLE. This is a very handsome large fine fruit, streaked with red on the side

next the sun, and of a yellowish colour on the other side. It is in eating from the latter end of September to December. I found this apple growing in the garden of the late Lord Godolphin, in St. James's Park; and have given it the name of the Godolphin apple, as I have not been able to find it in any Catalogue.

68. GRAVENSTEIN. *Hort. Soc. Tr.* 4. p. 523. t. 21. This is round, somewhat flattened, rather angular at the sides; the eye deeply sunk; skin smooth, of a fine clear straw-colour, streaked with red next the sun; flesh pale yellow, not fine in texture, juicy, with a high vinous sweet taste. It ripens the end of October, but will not keep after the end of November.

69. GREEN DRAGON. This is a fine large apple, of an excellent flavour, and pale-green colour. It is rather too large for the table, and is therefore mostly used as a kitchen apple. It keeps till March.

70. GREAT RUSSET. This is a middle-sized fruit, of a russet colour, with a little dark-red towards the sun. A pretty good apple, and keeps till April.

71. GRIDDLETON PIPPIN. This is a large angular-shaped apple, of a green colour, with a little blush towards the sun. It is a baking apple, and keeps till March.

72. GRUMAS'S PIPPIN. This is about the size and shape of a Golden Pippin; of a dingy-green

colour next the sun ; and of a dull yellow on the other side. It is ripe in January, and keeps till April.

73. HAGLOE CRAB. *Pom. Heref. t. 5.* This is a yellow-coloured conical-shaped apple, below the middle size. It is ripe in January ; but is only fit for making cider, or for baking.

74. HALL DOOR. This is a fine large apple, of a flat shape, beautifully streaked with red towards the sun, and of a greenish-yellow on the other side. This fruit is of a fine flavour, and is in eating from January till March.

76. HAMPSHIRE NONSUCH. This is a pretty large well-shaped apple, of a greenish-yellow colour, streaked with red. It keeps till the latter end of November.

77. HARVEY'S RUSSET, so called in Cornwall. This is a large russet-coloured apple, with a little red towards the sun. This is a famous kitchen fruit, and tolerably good raw. It has a musky flavour.

78. HAWTHORNDEN. *Hooker Pom. Lond. t. 44.* This is a large fruit, of a flat, ovate, angular shape ; the eye irregular, sometimes deeply sunk, and often inserted on the summit. It is of a delicate pale-green colour, when on the tree, covered with a glaucous bloom ; but when fully ripe, it becomes yellowish-white, with a beautiful pale-red tinge, generally on the side next the sun, which frequently becomes deeper as the fruit ripens. It is an early and great bearer, but is principally useful

as a kitchen fruit, the flavour not being high or very rich. It ripens in August and September.

79. HOLLAND PIPPIN. *Wyker Pippin*. *Langley Pom.* t. 79. f. 1. *Knoop Pom.* p. 41. t. 11. This is a middle-sized apple, of a flattish shape. Its colour is yellow, in some places inclining to green, with sometimes a little red towards the sun. This is a pretty good apple, and keeps till the middle of April.

75. HOLLINGBURY. This is a large flat-shaped apple, with large ridges from the base to the crown. It is of a beautiful red towards the sun, and of a yellowish colour on the other side and towards the eye. Said to be the same as *Kirke's Scarlet Admirable*.

80. HOLLOW-EYED PIPPIN. This is a middle-sized apple, of a yellowish colour, beautifully spotted with red towards the sun; and the eye is pretty deep. This is a good sharp-flavoured apple, and keeps till the middle of May.

81. HOLLOW-EYED RENNET OF CORNWALL. This is a handsome flat-shaped apple, under the middle size; of a greenish-yellow colour, sometimes intermixed with russet. This fruit is of an excellent flavour, and keeps till April.

82. HEDGE APPLE, a new fruit, of a middle size and handsome conical shape, red towards the sun, and a straw-colour on the other side. This apple is of a tolerably good flavour, and keeps till the latter end of April.

83. HOGSHEAD APPLE. This is a small red fruit ; the flesh is red, and the taste austere. This is a cider apple, ripe in January, and keeps till March.

84. HUBBARDS. *Russet Pearmain*. This is a real Norfolk apple ; and, though not handsome, is one of the best table apples. It is of a dark russet-colour ; ripe in January, and keeps till April.

85. HUGHES'S NEW GOLDEN PIPPIN. *Hooker Pom. Lond. t. 26*. This is a round fruit, compressed at both ends, resembling a flat Golden Pippin, but larger ; of a yellow colour, mixed with russet-brown, and much scarred ; the eye is small, slightly hollowed, with a few plaits round it. It is tinged with green at the stalk ; the flesh is yellow, sweet, and rich. It is ripe in December, and will keep to the end of January.

86. JULY FLOWER. *Listning. Langley Pom. t. 74. f. 5*. This is an angular-shaped apple, of the middle size, streaked with red towards the sun, and of a dull green on the other side : it is ripe in December, and keeps till the latter end of April. This seems to be a different apple from the Gilliflower already described.

87. JOHN APPLE. This is a middle-sized handsome fruit, of a green colour, with a little red towards the sun ; and the foot-stalk is very small. This is an excellent cider and baking apple, from Devonshire ; but was noted in Herefordshire in the time of Mr. John Phillips the poet. This

apple is of an excellent flavour, and keeps till March.

88. ISLE OF WIGHT PIPPIN. This is a handsome middle-sized apple, of a greenish-yellow colour.

89. JUNETING. *Jenneting. Langley Pom. t. 74. f. 2.* This is a small yellowish apple, red on the side next the sun. It is a pretty fruit for early variety, and ripens about the latter end of June or beginning of July.

90. KERNEL REDSTREAK. This is of a greenish-yellow, with broad streaks of a dark-red all over it, and a yellow ground, finely speckled with red next the sun.

91. KERNEL OF THE KENTISH PIPPIN. This is a handsome apple of a light-green colour, with a little red towards the sun. It is ripe about the middle of November.

92. KERNEL PEARMAIN. This is a small handsome apple, red towards the sun, and of a yellowish-green mixed with red on the other side. It is of a good flavour, and keeps till the middle of May.

93. KENTISH FILL-BASKET. This is a species of Codlin, of a large size, and is generally used for baking. It is in eating from August to October.

94. KENTISH PIPPIN. *Langley Pom. t. 79. f. 6.* This is a good-sized apple, finely streaked with red. It is of a fine flavour, comes into eating about Christmas, and keeps till February.

95. KENTISH NONPAREIL. This is a handsome

flat-shaped apple, of a light-russet colour, inclining to red towards the sun. It is of a good flavour, and keeps till May.

96. KERRY PIPPIN. *Hooker Pom. Lond. t. 20.* The fruit is usually of a globular shape, with some wrinkles about the eye. It is of a pale straw-colour, mixed with a deeper yellow; streaked and speckled with red, highly polished; the flesh is yellow, juicy, sweet, and well-flavoured. It has been long cultivated in Ireland. It ripens September and October.

97. KING OF THE PIPPINS. This is a middle-sized apple, of a fine gold colour, a little streaked with red towards the sun. It is ripe in January, and keeps till the latter end of March, but then becomes mealy.

98. KING APPLE. This is a middle-sized apple, of a conical shape; and its colour is that of a beautiful red intermixed with a little yellow on one side. This apple is of a pleasant sugary taste, and keeps till the latter end of April.

99. KIRKE'S SEEDLING. This is a large beautiful apple, of a fine red colour towards the base, and yellow towards the eye. The footstalk is slender, and the eye large.

100. KIRKE'S SCARLET PEARMAIN. This is a handsome middle-sized apple, of a beautiful red towards the sun, and a little yellow on the other side. It is ripe in January.

101. KIRKE'S SCARLET ADMIRABLE. This is a

good apple for baking, and of a beautiful scarlet colour; is in eating about the month of January. See Hollingbury.

102. KIRTON. *Crack'd Pippin. Langley Pom. t. 74. f. 4.* This is a middle-sized apple, of a greenish-yellow colour, with little dark spots. The coat is generally rough towards the foot-stalk. This is a good apple for the table, and comes into eating in September.

103. LADY'S FINGER. This is an excellent table apple, of a conical shape; red next the sun, and of a yellowish cast on the other side. It is of a sweet pleasant flavour, and keeps till May.

104. LAMB ABBEY PEARMAN. *Hort. Soc. Tr. 3. p. 269. t. 10. f. 2.* This is oval, somewhat pyramidal, rather flattened at both ends; the eye small, sunk in a deep broad hollow, surrounded with plaits; the skin yellowish-green on the shaded side and next the eye, but of a fine red with many black spots next the sun; flesh yellowish next the skin, green next the core, firm, crisp, very juicy, and has a peculiar rich sweetness and a slight aromatic flavour. It is in eating in November and December.

105. LARGE STIRE. This is a handsome cider apple, of a yellow colour, with a little red next the sun. It is ripe in November.

106. LEADINGTON, GREY. This is of a middle size, longish, and smaller towards the eye; of a dark-green or grey colour, and often speckled; the flesh is firm, melting, sweet, and agreeably per-

firmed. It is a hardy tree, grows regularly, and bears well. It will succeed on standards, dwarfs, or on a wall. There are several other sorts of Leadingtons.

107. LISBON PIPPIN. This is a handsome middle-sized apple, of a flat shape; a fine red towards the sun, and of a reddish-yellow on the other side. The flesh is firm, and has a sharp pleasant taste. It comes into eating in November.

108. LOAN'S PEARMAN. *Langley Pom. t. 76. f. 2.* This is a large oval-shaped apple, of a dull-green colour intermixed with a brownish-red, which is deepest next the sun. This is a pretty good table apple, of a sharp taste. It ripens in September, and keeps till May, but is apt to grow mealy.

109. LONDON PIPPIN. *Five-crowned Pippin.* This is a fine large apple, of a green colour, streaked with red towards the sun. This resembles a Ribston Pippin, but is larger. It has a pretty agreeable taste; and will come into eating about the latter end of November. Mr. Lindley calls this a real Norfolk apple; and says, it is one of the best that the country produces for kitchen and table, and a most abundant bearer. It keeps till the middle of April.

110. LONG LASTER. This is a middle-sized apple, of an angular shape, and fine yellow colour, with a beautiful red next the sun. It is of a tolerable flavour; and keeps till the middle of May, but is apt to be mealy.

111. LEMON PIPPIN. This is a handsome oval-

shaped apple, of a gold-colour. It is of a fine flavour, in eating in October, and will keep till the beginning of March. It is excellent for drying in an oven.

112. LONG SEAM. This is a large angular-shaped baking apple, of a pretty good flavour, and light-green colour. It keeps till the latter end of January.

113. LORD CHENEY'S GREEN. This is a middle-sized Yorkshire apple, resembling the Yorkshire Greening. It is of a dark green colour, with a little of a chocolate colour next the sun. This is a baking apple, and keeps till the middle of May.

114. LORD ARUNDEL'S APPLE. This is large, of an angular shape; the colour is green, with a little dingy-red towards the sun. This apple is from France; is good for sauce, and keeps well.

115. LORD CAMDEN'S RENNET (from Wilderness Park in Kent). This is a good-sized seedling of a yellow colour, with a little brownish red next the sun. This is a good-flavoured apple; and keeps till March.

116. LUCAS'S PIPPIN. This is a handsome middle-sized, cylindrical-shaped apple; and of a beautiful orange colour. A pretty good fruit, and keeps till the latter end of April.

117. MAIDEN'S BLUSH. This is a small apple, of a dark mahogany-colour next the sun, but paler on the other side, and sometimes of a greenish cast. The taste is austere, and of course this fruit is not fit for the table; but does very well for baking, or for cider. It keeps till the beginning of March.

118. MANSFIELD TART. This is a large Nottingham apple, but most known in Yorkshire. It is handsome and of a green colour, having a little cast of a brownish-red, with dark spots next the sun. A baking apple, and keeps till February.

119. MAY GENNET. This is rather under the middle size, of a greenish-yellow colour, slightly streaked with red next the sun. This apple keeps till April.

120. MAJOR HEMMINGS'S APPLE. This is a handsome middle-sized fruit, of a light-green colour, with a little brownish-red towards the sun. This is an excellent apple.

121. MARGILL. *Hooker Pom. Lond. t. 33.* This is an excellent apple, about the size of a Nonpareil. It is of a conical shape, pointed towards the eye, which is small and closely folded by prominent ribs; of a greenish-yellow colour, tinted with red, and streaked with a deeper colour next the sun, with some yellow or russet on the shaded side; the flesh is yellowish, rich, and spicy; it continues in use from November to the latter end of March; and is often sold in the London markets for a Nonpareil.

122. MARGARET APPLE. *Lammas; Red Juneting. Langley Pom. t. 74. f. 1.* This is a fine and beautiful fruit, yellow, striped with red, of a delicate taste, sweet scent, and is generally eaten off the tree. It is ripe in August.

123. MINIER'S DUMPLING. This is of a spherical shape, contracted towards the eye, and swelled into

a few imperfect angles, the colour is deep green, and very dark red next the sun: the flesh is firm, juicy, and high-flavoured. It is valuable for boiling or baking, and will keep till April.

124. MINCHALL CRAB. A handsome middle-sized Lancashire apple, of a yellow colour, with some brown spots. This is common in Manchester market. It keeps till April.

125. MONSTROUS RENNET. *Langley Pom. t. 78. f. 3.* This is a very large apple, of an oblong shape, turning red towards the sun, and of a dark green on the other side. It is generally preserved on account of its magnitude, as the flesh is apt to be mealy. It ripens in October.

126. MOTHER RENNET. This is rather under the middle size, of a greenish colour, with a little blush towards the sun. The eye is large and deep, and the footstalk is small.

127. NEW ENGLAND PIPPIN. A large angular-shaped apple, of a green colour, with a little brownish-red towards the sun. It has a pretty good flavour, and keeps till March.

128. NEWTOWN PIPPIN. *Grosse Reinette d'Angleterre. Duham. n. 21. tab. 12. f. 5.* This is an American apple, but said to be originally from Devonshire. It is a fine large apple, of a greenish-yellow colour, and red, with dark spots next the sun. When much exposed, it is of a beautiful red, towards the sun, and of a gold colour on the other side. This apple has a fine flavour, if it is not kept

till it is too ripe, when it becomes mealy. It is in eating from November to January.

129. **NEW RED MUST.** A fine large apple, of a pale red towards the foot-stalk, and of a greenish colour towards the eye. This is a Cider apple, and for baking.

130. **NEW RED PIPPIN.** This is a beautiful middle-sized apple, of a dark-red colour, with a mixture of yellow on the side from the sun. It keeps till March.

131. **NONSUCH.** This is a good bearer, and very fit either for the table or kitchen; the cooks, however, complain that it makes but a very small proportion of sauce. It is ripe in September and October.

132. **NONSUCH, BIGG'S.** This is shaped like the Nonsuch, but is broader at the stalk, and very hollow at the eye, of a deep yellow colour, striped with red next the sun, the flesh is pale yellow, soft, and tender. It bakes well, and will keep till Christmas.

133. **NINE SQUARE.** A Gloucestershire apple. This is a large angular-shaped fruit, of a fine red towards the sun, and yellow on the other side, with a small mixture of red. Keeps till April.

134. **NORFOLK COLMAN.** This is a middle-sized apple, of a mahogany colour towards the sun, and a dark green on the other side. It keeps till August.

135. **NORFOLK BEAUFIN.** This is a good-sized

apple, rather flattened, of a deep red colour towards the eye, but paler towards the foot-stalk.

136. NORFOLK PARADISE. This is a large apple, of a dark red colour towards the sun, and green on the other side. This is a nice baking apple, and of a tolerable flavour for eating. It keeps till the middle of May.

137. NORFOLK STORING. This is a pretty large apple, of a dark-red colour towards the foot-stalk, and green towards the eye. It is of a pleasant sharp flavour, and is in eating from the latter end of January to the latter end of April.

138. NORTHERN GREENING. This is a fine oblong apple, full at the foot-stalk, of a pale-green colour, with a little red towards the sun. It is nearly of an equal size from the base to the crown, and has a fine flavour. It is ripe in January.

139. NONPAREIL. *Langley Pom. t. 79. f. 4. Duham. n. 35. t. 12. f. 2.* This is a fruit deservedly valued for the briskness of its taste. It is seldom ripe before Christmas, and if well preserved, will keep till May. This is justly esteemed one of the best apples that have been yet known.

140. NONPAREIL, PITMASTON RUSSET. *Hort. Soc. Tran. 3. p. 267. t. 10. f. 4.* This is a flat compressed apple, narrowest at the head, the eye open, placed in a broad shallow cavity, with slight irregular plaits; the skin of a dull green, nearly covered with russet, with a little yellow and faint red on the side next the sun; the flesh is greenish-

yellow, firm, rich, and agreeably perfumed. It ripens in October and November.

141. NONPAREIL, BRADDICK'S. *Hort. Soc. Tr.* 3. p. 268. *t.* 10. *f.* 3. This is a flat globular apple; the eye small, placed in a deep smooth cavity; the skin is smooth, greenish near the stalk, tinged with yellowish-brown and brownish-red next the sun; and frequently a patch of fine russet round the eye; the flesh yellowish, sweeter, and more melting than the Nonpareil, though not very soft, richly sugared, and slightly aromatic.

142. NONPAREIL, SCARLET. *Hooker Pom. Lond.* *t.* 12. This is of a bright-red colour next the sun, streaked with brown, and green, tinged with russet-brown on the shaded side; the flesh is firm and excellent. It ripens in January, and will keep to the end of February.

143. OAK PEG. *Oaken Pin.* This is an oval-shaped middle-sized fruit, of a green colour striped with white. It is very full towards the foot-stalk, which is small; and keeps till June.

144. OLD ENGLISH PEARMAN. This is an oval-shaped apple, of a middle size, and fine red colour, with a little yellow towards the eye. It is of a pleasant sweet flavour; and is in eating from January to March.

145. OLD RED MUST. *Pom. Heref. t.* 4. This is a fine large apple, somewhat resembling the New Red Must, both in shape and colour, with the addition of dark red spots towards the foot-stalk.

146. OLD RED PIPPIN. This is a middle-sized

apple, red towards the sun, and of a greenish colour on the other side. This is a good apple, and keeps till March.

147. ORANGE PIPPIN. *Marigold Pippin. Pom. Heref. t. 8.* This is about the size of a large Golden Pippin; of a beautiful gold colour, with a little pale red towards the sun. This is a handsome apple, of a good flavour, and makes a fine appearance at table. It is in eating in October, and will keep till March, but gets flat in the taste when too long kept.

148. ORLEANS PIPPIN. This is a small flat-shaped apple, of a dark-red colour, resembling the Orleans Plum.

149. OSLIN PIPPIN. *Arbroath Pippin.* This is a large roundish apple, flat at both ends. It is of a light yellow colour, the flesh firm, and the juice sweet and pleasant. It grows freely from cuttings. Ripens in August.

150. PADLEY'S PIPPIN. This is of an oval shape, flat at the stalk, of a fine yellow colour, and pale rough skin; the flesh is firm, juicy, and perfumed. It is in eating in December and January.

151. PARADISE PIPPIN. *Magnum Apple.* This is a handsome middle-sized apple, of a reddish cast. It comes into eating in October, but will not keep. It grows mealy when too ripe.

152. PAWSAN. *Pom. Heref. tab. 15.* This apple is below the middle size, of a conical shape, and of a greenish yellow, or light-green colour. It is ripe in January.

153. PILE'S RUSSET. This is a middle-sized longish-shaped apple, russet about the foot-stalk, yellow towards the middle, and of a brownish-red about the eye. This is a very firm fruit, of a sharp acid flavour, and is much esteemed for baking. It ripens in October, and will keep till April.

154. PIGEONNET. *Duham. n. 26. Poit. et Turp. Fr. t. 80.* An apple rather below the middle size, of a conical shape. It is of a pink colour, pretty dark towards the sun. One received from the state of La Vilherie, near Morlaix, in Lower Brittany, by L'Abbé Joffrin, exactly corresponds with this description.

155. PEARSON'S PIPPIN. This is a nice apple, about the size of a large Golden Pippin, of a yellowish colour, and the form a little flat. In Devonshire they put these pippins into the oven just after the bread is drawn, laying a weight over them to flatten them, in the same manner as they do the Beaufin in Norfolk, and bring them to table as a sweetmeat. I brought some cuttings of this tree from Nutwell, near Exeter, which I grafted on some trees in Kensington-gardens. This is a very good dessert apple, and keeps till March.

156. POMME GRISE.\* This is a fine apple, from Canada, of a flattish form and russet colour,

\* The Pomme Grise was introduced into this country by Mr. Alexander Barclay, of Brompton, well known for his ingenuity in bleaching of wax. He is a great lover of horticulture, and has raised several new sorts of Gooseberries from seed.

streaked beautifully with red. It ripens late, and keeps till March. This is an excellent eating apple.

157. POMME D'API. *Duham. n. 30. t. 11. Poit. et Turp. Fr. t. 113.* This is much valued for its colour, being of a bright red next the sun, and yellowish-green on the other side. The tree is a good bearer, and the fruit is not subject to be shaken with high winds. The fruit should be suffered to hang on the tree till October or November, if the frost do not set in. It comes into eating in February and March, and keeps long; but is more admired for its beauty than its flavour.

158. POMME VIOLETTE. *Violet Apple. Duham. n. 7.* This is a pretty large fruit, of a pale-green, striped with red towards the sun. It has a sugary juice, and a flavour of violets, from which it takes its name. It ripens in October, and continues in eating till February.

159. POMROY. *King's Apple. Langley Pom. t. 79. f. 2.* This ripens nearly as soon as the Juneting; and though not so beautifully coloured, is larger and much better tasted. There is a variety which is a winter apple.

160. POUND PIPPIN. This is a large handsome apple, of a greenish colour; and is good for baking. It is ripe in January.

161. POOR MAN'S PROFIT. This is a dingy-coloured oval-shaped apple, below the middle size. It is raised freely from cuttings; and keeps till January.

*Knoop. Pom. p. 31. t. 9. Poit. et Turp. Fr. t. 189.*  
This is a middle-sized fruit, of a grey colour next the sun ; but mixed with yellow on the other side. It is a very good juicy apple, of a quick flavour, and ripens the latter end of October.

174. RED SWEET. This is a small round apple, red towards the sun, and of a greenish-yellow on the other side. This is a good bearer, and much esteemed among the country people of Cornwall, for making a kind of tart or pie, one of their dainties at Christmas. It is a pretty good table apple, and keeps till March.

175. RIBSTON PIPPIN. \* *Hooker Pom. Lond. t. 3.* This is a fine apple from Ribston Hall, near Knaresborough, Yorkshire. It is a little streaked with red towards the sun, and yellow on the other side. It is one of the best apples for eating and baking, and continues in use from the end of October till April. It bears very well as a dwarf, and no garden should be without it. The fruit is more broad than long, and broader at the bottom ; the eye is sunk, the leaflets of the calyx remaining black, and mostly closed. It is of a greenish-colour, but when fully ripe, changes to rich yellow, beautifully marked with red next the sun, in small dots and interrupted stripes.

176. ROBINSON'S PIPPIN. *Hooker Pom. Lond. t. 42.* This is about the size of a Golden Pippin,

\* The first tree of this kind was found growing in Sir Henry Goodricke's Park.

oval, flattened at both ends; the eye is open, and sunk in a broad but very shallow hollow; of a green colour, with a russet-brown, particularly about the eye, and partakes of the flavour both of a Golden Pippin and a Nonpareil; the flesh is green, breaking, and juicy. The fruit is produced in clusters, ripens in January, and will keep till May.

177. ROYAL GEORGE. This is a fine large apple, of a beautiful yellow on one side and green on the other. It is a good apple, and keeps till June, but then grows mealy.

178. ROYAL NONPAREIL. This is a handsome apple, of a flattish shape, with a small foot-stalk and fine eye. It is about the size of a common Nonpareil, of a green colour, with red towards the sun. It is ripe in January, and keeps till the latter end of March.

179. ROYAL PEARMAN. *Knoop Pom. p. 44. t. 12.* This is a fine large apple, beautifully streaked with red. It is ripe in January, and keeps till March. A pretty good apple.

180. ROYAL RUSSET. *Leather-coat Russet.* This is a large oblong fruit, broad towards the base, of a deep russet colour, and one of the best kitchen apples we have. It is also a pleasant eating apple, and a great bearer; and is in use from October to April.

181. RUSSET PIPPIN. This is of a rough russet colour towards the sun, and of a green colour, sometimes inclining to yellow, on the other side. This is a good keeping apple, and fit either for

oblong apple, of a carnation colour, and dark red towards the sun. This is a pretty good apple, and keeps till the beginning of May.

194. SPANISH ONION. This is a handsome round apple, of a russet colour, with a dull red towards the sun. This apple, which is rather below the middle size, is very good for the dessert, and keeps till March.

195. SHARP'S RUSSET. This is below the middle size, of a brownish-red colour towards the sun, and a pale green on the other side. It is shaped like the frustrum of a cone ; is of a pretty good flavour, and keeps till May.

196. SPENCER PIPPIN. *Langley Pom. t. 78. f. 5.* This is a middle-sized apple, of a yellowish colour, with many dark spots. A baking apple, and keeps till the middle of May.

197. TANKERTON. A conical-shaped yellow apple, with sometimes a little blush towards the sun. This is an excellent sauce-apple, and bakes well. It is of an agreeable taste, but too large for the table. It will keep till February.

198. TRANSPARENT APPLE. *Astrachan. Duham. n. 38.* This was introduced from St. Petersburg ; but is more curious than useful : a tree or two, therefore, will be sufficient for a garden. It ripens in September and October.

199. TREVOIDER RENNET. This is a small handsome russet-coloured apple, of an excellent flavour, and will keep till May.

200. VAN PIPPIN. This is a small round apple,

finely coloured with red and yellow; the pulp is sweet, juicy, and agreeable. The wood of the tree is weak, but it is hardy, and bears well.

201. **WHITE COURT-PENDU.** This is a middle-sized long-shaped apple, of a yellowish colour. It is a good eating apple, and ripens in January.

202. **WARD APPLE.** This is a beautiful flat-shaped apple, rather below the middle size, of a fine red towards the eye, and of a yellowish-green towards the footstalk. It is a sharp-flavoured fruit, and keeps till June.

203. **WHEELER'S RUSSET.** This is of a middling size, flat and round, of a pale russet colour next the sun, inclining to a pale yellow on the other side when ripe, the flesh firm, and of a quick acid flavour; it is an excellent kitchen fruit, and will keep long. It ripens in October, and keeps till May.

204. **WHEELER'S EXTREME.** This resembles the Pomme Grise, and is about the size of a Nonpareil. This is a flat-shaped apple, beautifully clouded with red on a yellowish-russet ground; is of an excellent flavour, and keeps till April.

205. **WHITE MUST.** This is a middle-sized handsome apple, of a greenish-yellow colour, with a little red towards the sun; the flavour is rather tart, but agreeable. It is ripe in January.

206. **WHITMORE PIPPIN.** This is a good-sized handsome apple, streaked with red towards the sun, and of a pale yellow on the other side. It has firm flesh of a tolerably good flavour, and is in eating from November to the latter end of April.

207. WILTSHIRE CAT'S HEAD. This is a large handsome apple, red towards the sun, and green on the other side. It is a very fine baking apple, and of a good flavour. It is ripe in January.

208. WILLIAMS'S PIPPIN. This is a conical-shaped apple, with a hollow eye and short stalk, of a pale yellow colour, with a little red next the sun; the flesh is pale yellow, soft and tender. It bakes and roasts well, and will keep till Christmas.

209. WINE RUSSET. This is a middle-sized conical-shaped apple, of a dark russet colour, and sharp flavour. It keeps till the latter end of April.

210. WINTER PEARMAN. *Hertfordshire Pearmain. Langley Pom. t. 78. f. 4. Knoop Pom. p. 39. t. 11. Pom. Heref. tab. 29.* This is of a fine red next the sun, and striped with red on the other side; the flesh is juicy and stews well. It is fit for use in November, and if properly managed will keep till the latter end of March.

211. WINTER POMROY. This is a pretty large conical-shaped apple, of a dark-green colour, a little streaked with red towards the sun. The coat is rather rough. It is a good baking apple, and keeps till January.

212. WINTER BOX-APPLE. This is a middle-sized fruit, of a light-green colour, and keeps till February.

213. WOODCOCK. *Pom. Heref. tab. 10.* This is a good-sized apple, of a dark-red next the sun, and paler, with a little mixture of yellow, on the

other side. It is ripe in January, and keeps till March. This is a good Cider apple.

214. WRIGHT'S NONPAREIL. This is a Salopian apple, great bearer, of a good size, and a little flattened. It is a good kitchen apple, and keeps till June. The tree is smaller in size than most other apple-trees.

215. YORKSHIRE GREENING. This is a good-sized flattened apple, of a dull-red colour, with a little green towards the eye. It keeps till August.

*Those in the following List marked thus \*, are most esteemed for eating raw; those †, for baking or boiling; and those ‡, for making of Cider. The words in Italic are names by which the preceding Fruit is frequently known.*

N. B. The Siberian Crab and the Double-blossom Crab are good for preserving.

*Sorts of Apples proper for a small Garden.*

The Juneting ; Golden Pippin ; Nonsuch ; Ribston Pippin ; Nonpareils ; Borsdorff ; Sykehouse ; Golden Rennet ; Aromatic Pippin ; Loan's Pearmain ; Royal Pearmain ; Lemon Pippin ; Pomme Grise ; Margill ; and French Crab ; different sorts of Russetins and Codlins for baking.

I have taken all the pains that I could to ascertain the real names of the best apples ; but the varieties are almost infinite ; it is therefore hoped that if the same apple should in some few instances be found under different names, it being almost impossible, amid such a variety, to avoid a mistake of that kind, the candid reader will have the goodness to view it with indulgence.

*On the Choosing, Planting, Pruning, and Training, of Apple-Trees.*

In choosing apple-trees from the nursery, it may

be sufficient to observe, that they, as well as Apricot and Peach-trees, should have strong, straight, and clean stems.

Sufficient instructions have already been given for preparing the borders and planting the trees ; which will also be applicable here. The same directions for heading must be observed, according to the season and time of the buds breaking forth, leaving the number according to the strength of each tree ; cutting as close as possible to the top bud, that the leading shoot may the more easily cover the wound ; and constantly observing to rub off all the buds that come up by the side of the leading shoot, which would otherwise rob it of its nourishment and strength, and so prevent it from making a fine leader. [*See PLATE VI. fig. 1.*] Remember to cut it annually to the length of from nine to eighteen inches, according to its strength, till the tree is got to that height to which you would have it run, and according to the extent of the ground ; which height may be from eight to twelve feet. By these means the trees will throw out horizontal branches on every side, and soon form handsome heads for dwarfs.

I would advise not to suffer the dwarf-trees to run higher than from eight to twelve feet ; otherwise they will become naked at bottom, the fruit will be liable to be blown down, and the tops broken by high winds.

In heading old decayed apple-trees, for the sake of symmetry, it will be necessary to cut at the forked branches as near as can be to the upper

side of the fork, cutting them in a sloping manner to carry off the wet, at the same time rounding the edges. You may begin at the lower branches, cutting just above the lower fork; and proceeding upwards, cut the rest of the branches from one to six joints, or forks, according to their strength, till you have finished cutting in the whole head. If any of these branches should have the canker, all the infected part must be cut out. When the tree is all prepared, apply the composition immediately, beginning at the top of the tree, and finishing with the powder of wood ashes and burnt bones, as you descend; which will save it from being rubbed off during the operation; and the composition will prevent the sun and air from injuring the naked inner bark. A tree thus prepared will, in the course of three or four years, produce more and finer fruit than a maiden tree that has been planted upwards of twenty years.

It is hoped, that the above directions, if properly attended to, will be sufficient to enable any one to bring old decayed trees into a healthy bearing state.

In large orchards and gardens, it may be necessary, at first, to head down only every other tree; cutting some of the branches of the rest, which are in a decayed and cankerous state, and will bear no fruit. This will be preparing them to throw out new wood, and furnish the tree much sooner with bearing branches. In such a season as the present (1800), when there is a blight and general failure of crop throughout the kingdom, the oper-

ation may be performed in Summer, in the months of May, June, and July, and even so late as August, which will save a season. As at this time gentlemen are generally in the country, they could have the pleasure of seeing this performed under their own direction. I would, however, recommend the performing the operation as early as possible: for by so doing the wood will be the stronger.

When the trees are become hollow, the same method should be followed as directed for Plums; but by no means cut them down unless the tops are quite decayed; observing to cut the loose rotten wood clean out of the hollow and other decayed parts, applying the composition. At the same time remember to open the ground, and cut out all the rotten parts that may be found in the lower part of the stem, together with all the decayed roots, which, if this be not done, will infallibly injure the fresh wood and bark, and prevent a cure from being effected.

I would recommend heading down all Apple-trees that are much cankered and have ill-shaped heads; for by so doing much labour will be saved, and the trees will amply pay the proprietor.

Never shorten the young branches, except they are very thin, when it will be necessary to do so to fill the trees with young wood: nor prune any of the young shoots the second year, (I mean the year after they are cut,) as many of the eyes, almost to the end of the shoot, will, if it be strong, become fruit-buds next year; and so on every year.

In the month of May in the first year after the trees have been so cut, it will be necessary to go over them, and rub off with your finger and thumb, all the superfluous young shoots; leaving from three to six eyes on each shoot, according to the size and strength of the branch cut. These shoots will bear from three to four years; by which time they will be pretty much exhausted by the great quantity of fruit produced from them; they should then be cut down to two eyes, to produce new wood.

I always leave three different years' branches on the trees. When the first shoot, *d*, is cut off at *e*, [See PLATE VI. *fig. 2.*] you will observe the next shoot, *f*, to be full of fruit-buds, if it has not been shortened; when it begins to grow weak, cut it off at *g*. The next cutting must be at *i*, when the branch *h* is tired of bearing. Proceed thus all over the tree with care and attention, and you will soon perceive the advantages of this method of pruning above the common mode, for by it you will be able to keep your trees in a constant state of bearing, which, if left to nature, would only produce a crop of fruit once in two or three years. Always remember, when the shoot that has done bearing is cut off, to apply the composition immediately, and to rub off the shoots where they are too numerous.

The best time to prune apple-trees is in the month of April, or in May, after the peaches, nectarines, and cherries are pruned. \*

\* Soon after this pruning, about the middle of May, it will be proper to look over the trees, and to pick off any caterpillars that may be on them.

You

The small shoots that cross each other should be cut off, leaving the strongest to fill up the tree, and make a fine handsome head. The suckers that spring from the root should be carefully grubbed up, and the side-shoots from the stem cut off; for, if left to grow, they will greatly weaken the tree. The knobs, where old branches have been cut off, should also be pared away, leaving the surface of the tree as smooth as possible; then apply the composition; the young bark will soon begin to grow, and by degrees cover the old wounds with a fresh smooth surface, and thus prevent the canker from gaining ground on the tree. I have seen some old wounds of considerable size healed over in one year.

The trees which I pruned and dressed, as above directed, in the course of the summer 1795, are all perfectly cured, the wounds being filled up with sound wood, and covered over with new bark: they all continue in a healthy state, and bear fine handsome fruit.

I have advised several nurserymen about London, particularly Messrs. Gray and Wear, at Brompton Park Nursery, Kensington Gore, and

---

You will then see what shoots are infected with the canker, and which might have escaped your notice at the time of pruning; and, wherever you observe the least appearance of infection, which may be known by the wood appearing of a brownish colour, the shoot must be cut down till you come to the sound white wood.

the late Mr. Malcolm of Stockwell, to head down their apple-trees after the season of drawing for sale is over.

Messrs. Gray and Wear have headed a great many of such trees as were formerly thrown to the faggot-pile, and have been amply recompensed for their trouble. Trees thus headed down, provided the stems be strong, will, in the first and second year, produce as much fruit as will refund the purchase money ; besides, a great deal of time will be saved, which would be lost by planting younger trees.

If you can procure trees of the above description that have been headed down three or more years, they will be all covered with fruit-buds, and, if carefully taken up and planted in the Autumn, if the season proves favourable, you will have a tolerable crop of fruit the first year. Such trees must not be headed down like maiden trees, but only thinned off where the branches run across and rub against one another, which should never be suffered.

From what has been said, I hope that gentlemen and others will not be blind to their own interest ; but that they will give the practice a fair trial, which, if properly executed, will not fail to turn out to their satisfaction. Independent of the great advantage to be derived from the increase of crops, instead of decayed, moss-grown trees, bearing only a few small hard and kernelly fruit, they will have the pleasure of seeing fine healthy

clean trees loaded with large beautiful and well-flavoured fruit; which, to those who have a taste for gardening and rural affairs, will be no small consideration.

I would never recommend training of apple-trees as Espaliers; for, by doing so, the air is kept from the quarters of the garden; and by constant pruning and cutting off all the side-shoots which you cannot tie to the espaliers, you prevent them from bearing, and moreover, bring on the canker.

When Dwarf-trees have handsome heads, you will get more and much finer fruit from one of them than from six Espaliers; at the same time a free air is admitted to the crops in the quarters, and the constant expence of stakes and labour, in laying the trees to the Espaliers, is saved.

Espaliers may be converted into Dwarf Standards by shortening the branches at different lengths, so as that they may be able to support themselves without the stakes; but not to shorten them all regularly; and if cut with judgment, as near to a leading shoot, or an eye, as possible, they will in the course of two years form fine heads, and in the third year will bear six times as much fruit as they did in their former state, and of a finer flavour.

The same method of pruning already laid down for Standard Apple-trees is also applicable to Espaliers.

The borders where you make your crossings in gardens should be six or eight feet broad at least,

to let the trees spread on each side, at the distance of twelve feet from tree to tree, and they should be well trenched, two feet and a half deep at least. If there should be gravel, or sour clay, it must be taken out, and good mould put in its place; leaving the ground as rough as possible, for the frost and rain to mellow it. When you level the ground, it should be done after rain; you may then sow some small crops in the borders, such as Lettuce or Spinage, or Cabbage for transplanting; but let not any of the Brassica tribe come to full growth. Leaving Cabbage and Broccoli on borders, near fruit-trees, draws the ground very much, fills the borders with insects, and also prevents the sun and air from penetrating into the ground.

When the sun can have free access to the border, it adds much to the flavour of the fruit. If you can spare the ground on the cross-borders in Winter, it will be of great service to the trees to ridge it up as loose as you can, and let it lie in that state all Winter, to mellow and sweeten.

If the soil be strong, I would recommend planting of apple-trees that are grafted on Paradise Stocks; but if the soil be light, free Stocks will do much better.

When the ground is a strong clay or brick earth, mix it with old lime-rubbish or coal-ashes, street-dung or sand: but what I use for the borders against the walls, and which I prefer to every other manure, is a vegetable mould produced from

leaves of trees, which may be obtained in the following manner :

Collect annually as many loads of leaves as you conveniently can, which make up into hot-beds for late Melons and Cucumbers and for early Potatoes, &c. First plant the beds with early Potatoes ; at the same time sow Radish and Lettuce seeds mixed together. When the Radishes are pulled, thin the Lettuces, leaving a sufficient quantity for a crop ; by the time the Lettuces are fit for cutting, the Potatoes begin to cover the bed. After the Lettuces are all cut, you should put some of the leaf-mould close up to the stems of the Potatoes, which will run very fast into the fresh manure, and produce a fine early crop. When you have dug up the Potatoes, take off all the fine vegetable mould till you come to the leaves that are not yet rotten ; then with a fork turn up the leaves, adding some fresh leaves at the same time, which will cause a fresh heat to come up in the bed ; when this is done, put on the lights and keep them close for three or four days : if the weather be fine and clear, there will, by that time, be a fine sweet gentle heat.

You may then sow or plant Melons or Cucumbers in the beds.

When the heat begins to decline, and the fruit to swell, put a fresh lining of leaves, two feet and a half broad, round the beds. The beds may be broken up the second Winter ; by which time you will find the top part of them rotted to a fine black

vegetable mould, which will be the best manure for the borders against the walls.

A good coat of this manure once in two or three years will be sufficient for the borders where the wall trees stand, and much better than dung, which I by no means approve of for trees, unless it be perfectly rotten and mixed up with mould.

Some of the leaves will be found not quite rotten at the bottom of the beds; these may be mixed up with fresh dry leaves from the park, garden, &c. and used for making new beds.

#### *Of Grafting old Apple-Trees.*

It frequently happens, that through some mistake or other, after waiting ten or twelve years for a tree to come into a bearing state, it is then found that the fruit is neither fit for the table nor kitchen; in such case, we always graft them the following Spring, observing to graft on the finest and healthiest shoots, and as near as possible to the old graft, and where the cross-shoots break out: by so doing, you will have some fruit the second year; and in the third, if properly managed, you will have as much as on a maiden tree of fifteen years' standing.

The canker, if any, must be carefully pared off the branch, and the scion must be taken from a sound healthy tree.

Whenever an incision is made for budding or grafting, from that moment the canker begins. I

would therefore recommend to those employed in budding or grafting, as soon as the incision is made, and the bud or graft inserted, to rub in with the finger, or a brush, some of the Composition before the bass is tied on ; then cover the bass all over with the composition as thick as it can be laid on with a brush, working it well in. If this operation be performed in a proper manner, and in a moist season, it will answer every purpose, without applying any grafting clay.

This I have frequently done, and found it succeed perfectly to my wishes. Observe not to slacken too soon the matting which is wrapped round the bud ; for in that case you will find the incision opened, which very often occasions the death of the bud.

If nurserymen and gardeners would give this method a fair trial, and use the same composition as I use for curing defects in trees, instead of loam and horse-dung, (which binds so hard as to prevent the rain and moisture from penetrating to the graft to moisten the wood and bark,) they would find that the grafts would succeed much better. The composition, for this purpose, should be rather softer than grafting clay generally is ; and, instead of applying so large a mass as is generally done of clay, it need not, in most cases, be more than two or three inches in circumference.

## CHAPTER VII.

## OF PEARS.

*Different Sorts of Pears described. — Of Planting, Heading, Pruning, &c. — Experiments on old Trees. — A comparative Statement of the Produce of Pear-Trees, by the old and new Way of Pruning and Training. — Of Trees headed down. — Remedy for the Canker, &c.*

THE cultivation of the Pear is undoubtedly of considerable antiquity ; - for Pliny mentions no less than twenty kinds, and Virgil five or six.

Linnæus arranges Pears along with Apples and Quinces, in the Fourth Order of his Twelfth Class ; Icosandria Pentagynia ; and is named *Pyrus Communis*.

The Pear-tree comprehends several varieties ; ripening in successive order from July to October.

*The Pears commonly propagated in England are as follow : viz.*

1. LITTLE MUSK PEAR. *Duham. n. 1. t. 1. Pom. Aust. t. 71. f. 1.*, commonly called the *Supreme*. This is very small and round, the fruit is generally produced in clusters, and when ripe is of a yellow colour, and brownish-red next the sun ; the flesh is yellowish, and the juice somewhat

musky; if gathered before it be too ripe, it is a good pear. It ripens about the latter end of July, and continues good only a few days.

2. CHIO. *Little Bastard Musk*. This is pretty much like the other, but smaller, and the fruit does not hang in clusters. The skin, when ripe, has a few streaks of red next the sun.

3. GREEN CHISSEL. *Langley Pom. t. 62. f. 2*. This is a middle-sized fruit, somewhat longish, and tapering towards the stalk; it always remains green, and is full of juice when ripe. It ripens the beginning of August. It is a good bearer.

4. CITRON DE CARMES. *Magdalen. Duham. n. 7. t. 4. Pom. Aust. t. 73. f. 1. Poit. et Turp. Fr. t. 61*. This is a small-sized pear, of a yellowish-green colour, and sometimes faintly stained with red next the sun; full at the eye, of a round shape, but tapering a little towards the stalk, which is long; the flesh is white, melting, not gritty; the juice is slightly perfumed. When over-ripe it becomes mealy. It ripens in July.

5. RED MUSCADELLE. *Bellissime d'Été. Suprême. Duham. n. 80. t. 42. Pom. Aust. t. 80*. This is a large early pear, of great beauty; the skin is of a beautiful yellow, striped with red, and the flesh has a rich flavour. This sometimes produces two crops in a year; the first about the end of July, and the second in September.

6. LITTLE MUSCAT. *Poit. et Turp. Fr. t. 65*. This is a small pear, more round than long; the skin is very thin, and of a yellowish colour when

ripe. This fruit has a rich musky flavour, but will not keep long. It is ripe about the beginning of August.

7. CUISSE MADAME. *Lady's Thigh. Duham. n. 11. t. 5. Langley Pom. t. 61. f. 4. Knoop Pom. p. 64. t. 5. Pom. Aust. t. 74?* This is a long pyramidal-shaped pear, with a long stalk; the skin is all over shining and fine, of a greenish-yellow colour from the sun, but towards it inclining to a deep brown colour; the flesh is breaking, and has a rich musky flavour. It is ripe about the middle of August.

8. WINDSOR. *Langley Pom. t. 61. f. 2. Knoop Pom. p. 50. t. 1.* This is an oblong fruit, broad at the crown, and tapering to a point at the stalk; it has a smooth skin, and when ripe is of a yellowish-green colour; the flesh is very soft, and if permitted to hang but two or three days after it is ripe, grows mealy, and is good for nothing. It becomes ripe about the latter end of August.

9. JARGONELLE. *Duham. n. 6. Langley Pom. t. 61. f. 3. Knoop Pom. p. 63. t. 4.* This is a middle-sized pear, of a long shape, with a large eye, tapering towards the stalk, which is long; the skin is of a bright yellow on the shaded side, and of a deep red or brown colour next the sun; the flesh is white, fine, and rather crisp; and the juice a little musky; it is somewhat like the Windsor, but not so broad at the crown, and is smaller towards the stalk; the skin is smooth, and of a pale-green colour. This is a plentiful bearer; but the

flesh is apt to be mealy, if it stands to be ripe, which is about the middle or end of August. This pear bears best on standards.

10. EPARGNE. *Beau Present. Saint Samson. Grosse Cuisse Madame. Duham. n. 17. t. 7. Knoop Pom. p. 64. t. 5. Pom. Aust. t. 77. Poit. et Turp. Fr. t. 38.* This is a large long pear, tapering towards the stalk, of a yellowish-green colour on the shaded side, and sometimes washed with red next the sun; of a russet-colour around the stalk, and covered with brown spots; the flesh is melting, tender, and juicy. It ripens about the middle of August.

11. ORANGE MUSK. *Duham. n. 25. t. 10. Pom. Aust. t. 86. f. 2.* This is a middle size, and short, globular form; of a yellow colour when ripe, and spotted with black; the flesh is musky, but very apt to be dry. It ripens about the latter end of August.

12. GREAT BLANQUET. *Bagpipe of Anjou. Duham. n. 13. Pom Aust. t. 75. f. 1. Poit. et Turp. Fr. t. 68.* This is a large roundish pear, with a smooth skin of a pale-green colour, and some bright red next the sun; the flesh is soft, and full of juice of a rich flavour. It ripens about the middle of August.

13. LITTLE BLANQUET. *Musk Blanquet. Pearl Pear. Duham. n. 16. t. 6. Langley Pom. t. 62. f. 3. Pom. Aust. t. 76. f. 2. Poit. et Turp. Fr. t. 112.* This is much less than the former; of a pale-green, inclining to a yellow colour, smooth,

and as if transparent ; the flesh is white, tender, and full of a rich musky juice. It ripens about the latter end of August.

14. LONG-STALKED BLANQUET. *Duham. n. 15. t. 6. f. B. Pom. Aust. t. 75. f. 2. Poit. et Turp. Fr. t. 77.* This fruit grows in clusters. It is like the former, with a larger and more hollow eye ; it is full towards the stalk, and a little crooked : it has a very smooth skin, white or greenish, and a little coloured with russet towards the sun ; and full of a rich sugary juice. It is ripe at the latter end of August.

15. EARLY ROUSSELET. *Cyprus Pear. Duham. n. 33. Pom. Aust. t. 73. f. 2.* This is a small tapering fruit, of a yellow colour, bright red, with grey spots next the sun ; the flesh is a little yellow, rather crisp, with very small stones round the kernels ; the juice perfumed, and sugary. It ripens in August.

16. SKINLESS. *Fleur de Guignes. Duham. n. 35. t. 13. Pom. Aust. t. 81. f. 1.* This pear resembles the Early Rousselet, but is rather longer ; of a greenish-yellow colour, with grey spots on the shaded side, and pale-red next the sun ; the flesh is melting, and the juice very good, sweet, and perfumed. It ripens in the middle of August.

17. MUSCAT ROBERT. *Queen's Pear. Amber. Duham. n. 3. t. 2. Pom. Aust. t. 72. f. 1.* This is a middling size, tapering to the stalk ; the skin is smooth, of a bright yellowish-green colour ; the flesh is tender, and the juice sugary and well fla-

voured. It is a great bearer. This pear ripens about the latter end of August.

18. MUSK DRONE. *Bourdon Musqué. Duham. n. 27. Pom. Aust. t. 79. f. 2. Knoop Pom. p. 65. t. 5.* This is a small fruit, almost round, flat at the top, of a bright greenish-yellow colour, marked with very small dots of a deeper green; the flesh is white, crisp, and has a rich musky taste; but it is apt to grow mealy, if left too long on the tree. It ripens the end of August.

19. RED ORANGE. *Orange-rouge. Duham. n. 26. Knoop Pom. p. 61. t. 4. Pom. Aust. t. 85. Poit. et Turp. Fr. t. 191.* This is a middle-sized round fruit, with a very hollow eye and short stalk, of a greenish-yellow colour; but the side next the sun changes to a deep red or purple colour when ripe; the flesh is melting, and the juice sugary with a little perfume, but is apt to be woolly when the fruit ripens on the tree. It ripens the beginning of August.

20. MUSK ORANGE. *Duham. n. 25. t. 10. Pom. Aust. t. 86. f. 2.* This is a middle-sized fruit, of the shape of an orange, rather flattened, and covered entirely with little hollows, of a yellowish-green colour, with a very little red; the flesh is melting, musky, but becomes woolly, if not gathered green. It ripens the beginning of September.

21. CASSOLETTE. *Green Muscat. Duham. n. 44. t. 18. Pom. Aust. t. 91. f. 2.* This is a small pear, of a long shape, round at the head, and thickish at the stalk; of a yellowish-green colour, with pale-

red on the sun side, and some specks on the skin ; it is full of a rich perfumed juice, and ripens in the beginning of September.

22. GREAT ONION. *Brown Admired. Summer Archduke. Duham. n. 19. t. 8. Pom. Aust. t. 78. f. 1.* This is a middle-sized round pear, of a yellow colour on the shaded side, smooth, shining, and brownish-red next the sun ; the flesh is partly crisp, often gritty, the juice high and rose-flavoured. It is ripe the end of August.

23. AVERAT. *August Muscat. Robine. Royale d'Eté. Duham. n. 56. t. 27. Pom. Aust. t. 89. f. 1.* This is a roundish flat pear, in shape very like a Bergamot ; the eye is a little hollowed, and the stalk is long, straight, and somewhat spotted ; it has a smooth skin, of a whitish-yellow colour, speckled with brown-green, and when full ripe yellow and reddish ; the flesh is white, crisp, but not dry, and its juice richly sugared and perfumed. It is a great bearer, and esteemed one of the best summer-pears. It ripens the end of August, or beginning of September.

24. ROSE. *Epine Rose. Duham. n. 57. Pom. Aust. t. 84.* This is a large, round flat pear, shaped like the Great Onion, of a yellowish-green colour, speckled and marbled with brown, and on the side next the sun, it is brownish-red. The flesh is white, breaking, and the juice musky and sugary. It ripens the beginning of September.

25. POIRE DU BOUCHET. This is a large, round, whitish pear, and shaped somewhat like the Besi-

deri; the flesh is soft and tender, and the juice sugary. It ripens the beginning of September.

26. PERFUMED. *Duham. n. 20. Pom. Aust. t. 81. f. 2.* This is a middle-sized round fruit, with a somewhat thick and tough skin, of a deep red colour with yellow dots, and on the shaded side of a yellow citron spotted with brown; the flesh is melting, but dry, and has a perfumed flavour. It is ripe the end of August.

27. SALVIATI. *Duham. n. 21. t. 9. Langley Pom. t. 64. f. 5. Pom. Aust. t. 86. f. 1.* This is a large, round and flat pear; the stalk is very long and slender, and the fruit is a little hollowed both at the eye and stalk; it is of a beautiful yellow wax colour, with a little red on the sun side; the skin is rough, the flesh tender, but soft, and has no core; the juice is sugary and perfumed. It ripens about the middle of September.

28. ROSE WATER PEAR. *Caillot Rosat. Duh. v. 2. p. 177.* This is a large round pear, like the Messire Jean. The stalk is very short, and the fruit is hollowed like an apple at the stalk; the skin is rough and of a brown colour; the flesh breaking, and the juice very sweet. It ripens the end of September.

29. GREAT ROUSSELET. *Roi d'Eté. Duham. n. 34. t. 12. Langley Pom. t. 65. f. 4. Pom. Aust. t. 90.* This is a large oblong pear; the skin is rough, dotted with small grey spots of a deep green on the shady side, and brownish-red on the other; the flesh is soft and tender, without much core, the

juice agreeably perfumed, if gathered before too ripe. It produces larger fruit on espaliers than on standard trees. It ripens the middle of September.

30. GREAT MOUTHWATER. *Gros Mouille-bouche*. This is a large round pear, with a smooth green skin; the stalk is short and thick; the flesh melting and full of juice, if gathered before it is too ripe, otherwise it is apt to grow meally. It ripens the middle of September.

31. THE PRINCE'S PEAR. *Poire de Prince*. This is a small roundish pear, of a bright red colour next the sun, but of a yellowish colour on the other side; the flesh is between breaking and melting; the juice is very high-flavoured. It is a great bearer, and ripens the middle of September, but will keep a fortnight good, which few summer-pears will do. It is said to be the same with the next.

32. CHAIR A DAME. *Duham. n. 41. t. 16. Knoop Pom. p. 66. t. 5. Pom. Aust. t. 82. f. 1.* This is of a middle size, rather long; the skin grey, of an Isabella colour, a little tinged with red on the side next the sun. When very ripe, it is yellow streaked with grey, and marbled with a bright red; the flesh half breaking, the juice sweet, heightened with a little agreeable perfume. It ripens the end of August, or beginning of September.

33. SUMMER BERGAMOT. *Milan. Langley Pom. t. 65. f. 3. Duham. n. 45. Pom. Aust. t. 97. f. 2. Poit. et Turp. Fr. t. 148.* This is sometimes called

*Hamden's Bergamot.* This is a large, round, flat pear, hollowed a little at both ends like an apple; the skin is rough, of a greenish-yellow colour, and sometimes brownish-red next the sun; the flesh is melting, and the juice highly perfumed. It is ripe about the middle of September.

34. AUTUMN BERGAMOT. *Holland Bergamot. Heere Pear. Knoop Pom. p. 52. t. 2. Duham. n. 48. t. 21. and t. 19. f. 7. Pom. Aust. t. 115.* This is a smaller pear than the former, but nearly of the same shape; the skin is smooth and green, but turns yellow when ripe. On the side next the sun it is lightly tinged with brownish-red, speckled with grey spots; the flesh is melting, and the juice richly perfumed. It is a great bearer, ripens the end of September, or beginning of October, and is one of the best pears of the season.

35. SWISS BERGAMOT. *Duham. n. 47. t. 20. Langley Pom. t. 63. f. 8. Pom. Aust. t. 114.* This is somewhat rounder than either of the former; the skin is tough, of a green and yellow colour, striped with red; the flesh is melting and full of juice, but not so richly perfumed as either of the two former. It ripens the beginning of October.

36. GANSEL'S BERGAMOT. *Ives Bergamot. Bon Rouge. Hooker Pom. Lond. t. 17.* This is a large roundish-shaped fruit, of a russet-green colour, and deep brown red next the sun, and scarred; the eye is open and slightly hollowed; the pulp is rich, sweet, and juicy; it never decays internally. It is a shy bearer, but succeeds best on standards.

It is ripe from the middle of October to the middle of November.

37. SUMMER BONCHRÊTIEN. *Gracioli. Duham. n. 90. t. 47. f. 4. Langley Pom. t. 65. f. 2. Pom. Aust. t. 87. Poit. et Turp. Fr. t. 110.* This is a large oblong fruit with a smooth and thin skin; of a bright green colour, spotted with darker green and yellow, when ripe; the flesh is white, tender, and half-breaking, and is very full of juice, which is of a rich perfumed flavour. It ripens about the middle of September.

38. WILLIAMS'S BONCHRÊTIEN. *Hort. Soc. Tr. 2. p. 250. tab. 16.* This is a seedling pear (from Williams's nursery at Turnham-Green,) originally from Berkshire. It resembles a summer Bonchrêtien, but is more juicy; it is a great bearer, and ripens in (August on walls) September. This pear will be a valuable acquisition to the market-gardeners, as it immediately succeeds the Windsor pear. It is of a large irregular pyramidal shape; the eye not sunk, of a pale-green colour, spotted with darker green and russet brown, turning yellowish, and faintly tinged with red next the sun when fully ripe; the flesh whitish, tender, and full of sweet and perfumed juice.

39. BEURRÉ ROUGE. *Red Butter Pear. Duham. n. 75. t. 38. Langley Pom. t. 64. f. 6. Knoop. Pom. p. 71. t. 7. Pom. Aust. t. 103.* The red, the grey, and the green Beurré, are all the same sort of pear: the difference in colour arising from the stock, the soil, or situation. It is a large long

fruit, for the most part of a reddish-brown colour; the flesh is fine, delicate, melting, and full of a rich sugary juice, without even being mealy. It ripens the beginning of October, and when first gathered from the tree is one of the very best sort of pears we have. It bears well and suits most soils.

40. BROWN BEURRÉ. *Beurré d'Angleterre*. *Duham. n. 76. t. 39. Knoop Pom. p. 67. t. 6. Pom. Aust. t. 102. Poit. et Turp. Fr. t. 127. Hooker Pom. Lond. t. 27.* This pear is of an irregular, long oval shape, tapering to a point next the stalk; the eye is deep sunk; it is of a fine russet brown colour, yellowish and dull red next the sun, and a little tinged with green on the shaded side; the flesh is melting, sweet, somewhat perfumed, and full of a rich juice. It frequently decays at the core. It ripens in October, and is justly esteemed an excellent pear.

41. GOLDEN BEURRÉ. This is a very fine pear; it is of a beautiful scarlet colour next the sun; and of a gold-colour on the other side: the flesh is melting, and the juice high-flavoured. It ripens in October. This tree succeeds best on an east aspect and a loamy soil. It is a plentiful bearer.\*

42. TRUE GOLDEN BEURRÉ. This in shape and size resembles the Brown Beurré, but is of a red-

\* This pear was introduced from Burgundy by the late Marshal Conway, and was first raised, in this country, at his seat of Park Place, near Henley upon Thames, now the seat of Lord Malmesbury. The above description was transmitted to me by Mr. Copeland, his Lordship's gardener.

dish-brown colour next the sun. A very fine pear, but will not keep long. It comes into eating in October.

43. DOYENNÉ. *Dean's Pear*; *Carlisle*; *White Beurré*; *Saint Michel*; *Valentia*. *Duham. n. 81. t. 43. Langley Pom. t. 62. f. 6. Pom. Aust. t. 107. Poit. et Turp. Fr. t. 82.* This pear varies much in shape, sometimes it is nearly round, and at other times long; the skin is smooth, of a pale yellow or citron colour, with faint scarlet next the sun; the flesh is white, melting, and full of juice, which is very cold; hence it has been called *Poire de Neige*. It will not keep good a week after it is gathered, being subject to grow mealy. It is a great bearer, and ripens the beginning of October.

44. DOYENNÉ GRIS, OU D'AUTOMNE. *Duham. n. 84. t. 47. f. 1. Pom. Aust. t. 108. Poit. et Turp. Fr. t. 100. Hort. Soc. Trans. 5. p. 136. t. 2. f. 1.* This is of a middle size, nearly round, like the former in shape, but not so large; the eye is small, close, and slightly hollowed; it is of a russet grey or bright cinnamon colour; the flesh is melting and not liable to be mealy; the juice is sugary, more crisp, and of a much finer flavour than the *Doyenné Blanc*. It ripens the beginning of November, nearly a month after the other.

45. VERTE-LONGUE. *Long Green Pear*; *Autumn Mouthwater*. *Duham. n. 73. Langley Pom. t. 63. f. 5. Poit. et Turp. Fr. t. 84.* This is a large long fruit; the skin is green even when ripe, marked with small brown dots; the flesh is very

melting, delicate, and white, not gritty, but soon grows soft; the juice is plentiful, sweet, sugary, and perfumed. It ripens about the end of October.

46. VERTE-LONGUE, Striped, or Swiss. *Duham. n. 74. t. 37. Langley Pom. t. 63. f. 6. Pom. Aust. t. 159.* This is a variety of the last, but not so large, with stripes of yellow and green, and speckled with brown or dark green, sometimes a little washed with red next the sun. In very dry soils some of the leaves are striped. It ripens the end of October.

47. SWAN'S EGG. *Langley Pom. t. 64. f. 4. Duham. n. 42. ? Pom. Aust. t. 128.* This is a middle-sized pear, nearly of the shape of an egg; the skin is green on the shaded side, a little yellow like the Verte-longue, but sprinkled with russet spots, and of a reddish colour mixt with green on the side next the sun; the flesh is fine, half melting; sometimes tender and half buttery, the juice sugary, sweet, a little musky, and of an agreeable taste without sharpness. It comes into eating in November. The tree is healthy and bears well either as a standard, or any other way.

48. ASTON TOWN. *Hooker Pom. Lond. t. 18.* This somewhat resembles the Swan's Egg, but tapers more towards the stalk, and is rather flattened at the other end; it is of a greenish-yellow colour, spotted with russet and a few large spots of dark brown when fully ripe; the flesh is melting, perfumed, and high-flavoured, but sometimes a little stony. It is ripe in November, but will not keep long.

49. WHITE AND GREY MONSIEUR JOHN. *Messire Jean, Duham. n. 55. t. 26. Langley Pom. t. 66. f. 1. Pom. Aust. t. 141. and 156. Poit. et Turp. Fr. t. 43.* These are the same; the difference of their colour proceeding from the different soils and situations wherein they grow, or the stocks on which they are grafted. If this pear be rightly managed, there are not many sorts in the same season to be compared with it. It is a large round fruit, sometimes longish; the skin is rough and coarse, of a yellowish colour, covered nearly all over with brown spots; the flesh is breaking; sometimes a little stony, and subject to grow soft; the juice is rich, sugary, and high flavoured. It ripens the end of October or beginning of November.

50. FLOWERED AUTUMN MUSCAT. *Knoop Pom. p. 65. t. 5.* This is an excellent pear, of a middle size, round, and of a dark-red colour; the flesh is very tender, and of a delicate flavour. It ripens the end of October.

51. BEZY DE LA MOTTE. *Duham. n. 82. t. 44. f. 5. Pom. Aust. t. 104. Hort. Soc. Trans. 5. p. 132. t. 2. f. 2.* This is a large pear, sometimes resembling the Crasanne in shape, but the stalk is not so long; the skin is dark-green, much spotted with grey or dark-russet, and turns a little yellow when ripe; the flesh is very white, melting, not gritty, the juice sugary, and high flavoured. It is a good bearer, and the tree retains its spines. It

ripens the end of October or beginning of November.

52. BEZY DE MONTIGNY. *Duham. n. 83. t. 44. f. 6. Pom. Aust. t. 109.* This is a middle-sized fruit, and longish, somewhat resembling the Doyenné; the skin very smooth, of a bright green, turning to a fine yellow when ripe; the flesh is white, not gritty, melting, with a very agreeable musky flavour. It ripens the beginning of October.

53. FRANGIPANE. *Franchipane. Duham. n. 85. t. 47. f. 2. Pom. Aust. t. 121. Poit. et Turp. Fr. t. 33.* This is of a middle size, somewhat resembling the Windsor pear, but smaller; the skin is smooth, a little oily to the touch, and covered with minute green spots; of a clear yellow, nearly lemon-colour on the shaded side, and bright red next the sun; the flesh is white, crisp, partly melting; the juice sweet and sugary, and of a taste like the Patisserie, called Franchipane. It is ripe the end of October or beginning of November. The tree is a good bearer, and the fruit is produced in clusters.

54. VINE PEAR. *Demoiselle. Duham. n. 110. t. 58. f. 2. Pom. Aust. t. 135. f. 1.* This is a small round fruit, the stalk very long and slender; the skin is rough, of a brownish-grey colour, tinged with red next the sun, and covered with small grey dots; the flesh is very melting, and full of a clammy high-flavoured juice; the fruit should be

gathered before it is too ripe, otherwise it grows mealy, and soon decays. It comes into eating the end of October or beginning of November.

55. ROUSSELINE. *Duham. n. 37. t. 15. Pom. Aust. t. 135. f. 2.* This is shaped like the Rousset, but the skin has much brighter colours; it is smooth, of a greenish-yellow on the shaded side, but of a deep red colour next the sun, with some spots of grey; the flesh is fine, tender, and delicate; the juice sugary, musky, and very agreeable. It ripens the end of October, but must not be kept too long, as it decays in the middle.

56. PENDART. *Knave's Pear.* This is like the Cassolette, but is somewhat larger; the flesh is fine and tender, and the juice very much sugared. It ripens the end of October.

57. MARQUISE. *Duham. n. 93. t. 49. Langley Pom. t. 68. f. 4. Pom. Aust. t. 138.* This is a large pyramidal pear, flat at the top; the eye is small, and hollowed, the skin is of a greenish-yellow colour, spotted, and a little tinged with red next the sun. If this pear does not change yellow in ripening, it is seldom good, but when it does, the flesh will be melting, tender, and the juice sugary, sweet, and sometimes a little musky. It is ripe in November and December.

58. CHAT BRULÉ. *The Burnt Cat. Duham. n. 116. Poit. et Turp. Fr. t. 152.* This is a small oblong pear, like the Martin Sec, but is something larger, and the colour of its skin is a more dusky brown; it is very smooth and shining; the

flesh is tender, but dry, and if kept a short time is apt to grow mealy. It is an inferior fruit for the dessert, and has many superior as a Compote Pear. It ripens the beginning of November.

59. BEZY D'HERY. *Duham. n. 23. Langley Pom. t. 66. f. 3. Pom. Aust. t. 152.* This is a middle-sized round pear, of a pale-green, inclining to a clear yellow colour; the flesh is unusually white, dry, and very indifferent for eating, but it bakes well. It ripens the middle of November, and will keep till December.

60. CRASANNE. *Duham. n. 49. t. 22. Pom. Aust. t. 111. Hooker Pom. Lond. t. 35.* This is a middle-sized pear, hollowed at the crown like an apple. It is of a dull-green colour, mixed with russet, and spotted all over; of a roundish shape, turbinated, and tapering towards the stalk, which is long, dark-brown, and curved; the flesh is extremely tender, and buttery, and full of a rich sugared juice. It is the very best pear of the season, and comes into eating in November and December.

61. LANSAC. *Dauphiné, Satin. Duham. n. 109. t. 57. Langley Pom. t. 67. f. 5. Pom. Aust. t. 122.* This is a roundish pear, flat at the top, but a little tapering towards the stalk; the skin is smooth, and of a yellowish-green colour; the flesh is yellow, tender, and melting; the juice sugared, and a little perfumed. It ripens in November, and will keep till January.

62. MARTIN SEC. *The Dry Martin. Duham.*

*n. 36. t. 14. Langley Pom. t. 72. f. 1. Pom. Aust. t. 137. Poit. et Turp. Fr. t. 108.* This is almost like the Rousselet in shape and colour. It is an oblong pear, of a deep russet-colour on the shaded side, and bright red on the other; the flesh is breaking, and tolerably fine, sometimes a little stony; the juice sugary, a little perfumed, and agreeable. It ripens the end of November, and if permitted to hang the full time on the tree, will keep till January or February.

63. BIGARRADE. *Orange Tulipé. Duham. n. 79. t. 41. Pom. Aust. t. 101. Poit. et Turp. Fr. t. 58.* This is a large round pear, with a very long slender stalk, the skin of a yellowish-green on the shaded side, and brownish-red on the other; between the green and brown red, there are stripes of red, and it is spotted all over with grey; the flesh is breaking, but not very full of juice. It is in eating the end of November.

64. AMADOT. *Pom. Aust. t. 166.* This is a middle-sized pear, longish, but flat at the top, with a rough skin, of a russet-colour next the sun, and yellowish green on the other side; the flesh is dry, but high-flavoured. This tree retains its thorns, and is esteemed for grafting the melting pears upon, as it gives them some of its fine musky flavour. It is in eating the beginning of December, and will keep good six weeks.

65. MERVEILLE D'HIVER. *Petit Oin. Little Lard Pear. Duham. n. 67. t. 33. Pom. Aust. t. 139.* This is a middle-sized fruit, but not con-

stant in its shape, sometimes resembling the Ambrette or Echassery, at other times the Bergamot; the skin is a little rough, greenish, sometimes spotted, and has often small knots on it, and turns somewhat yellow when ripe. The stalk is pretty long and slender, and the eye large and deeply hollowed; the flesh is very fine, melting, and not gritty; the juice much sugared, and has an agreeable musky flavour. It is in eating the beginning of December, and is esteemed one of the best fruits in that season.

66. LOUISE BONNE. *Duham. n. 97. t. 53. Pom. Aust. t. 134.* This is a large long fruit, the stalk short, fleshy, and somewhat bent; the eye very small; the skin very smooth, sprinkled with dots, and small spots, of a greenish colour, but turns white when ripe; the flesh extremely tender and full of juice, which is very sweet, especially on dry soils. It ripens the end of November and beginning of December.

67. COLMAR. *Poire-Manne. Belle-et-Bonne. Duham. n. 94. t. 50. Pom. Aust. t. 125. Hooker Pom. Lond. t. 19.* This is a large fruit, a little flattened at the eye, which is small and hollowed; it is larger in the middle than at the head, and diminishes to the stalk, which is brown, thick, and a little bent. It is of a green colour, with small brown dots, and becomes yellow when ripe. It has sometimes a little red next the sun. The flesh greenish-white, a little yellowish, very tender, and the juice greatly sugared. It is in eating about

the beginning of January, and lasts all February and part of March, and is esteemed an excellent fruit.

68. PEAR D'AUCH. This was introduced by the late Duke of Northumberland about 1767. It much resembles the Colmar, but is fuller towards the stalk. It is in eating from Christmas to April, and is, without exception, the best of all the winter pears. It is a more abundant bearer than the Colmar.

69. ESCHASSERY. *Yat or Yut Pear. Duham. n. 66. t. 32. Langley Pom. t. 70. f. 1. Pom. Aust. t. 118. Knoop Pom. p. 71. t. 7.* This is a middle-sized fruit, round, oval, tapering towards the stalk, and sometimes shaped like a Citron; the skin is smooth and of a green colour, with a little brown next the sun while it hangs on the tree, but turns yellow as it ripens; the stalk is straight and long, the eye small and not hollowed; the flesh is melting, buttery, and fine; the juice sugary, musky, and of a very agreeable flavour. It ripens in December, and will keep all January. It bears best on standards, and produces its fruit in clusters.

70. VIRGOLEUSE. *Chambrette. Duham. n. 95. t. 51. Langley Pom. t. 67. f. 2. Pom. Aust. t. 147.* This is a large long pear; the stalk is short, fleshy, and a little bent; the eye of a small size, a little hollowed; the skin smooth, with some small dots of a russet colour, at first green, then yellowish, like a Citron, and as it ripens, generally takes a slight tinge of red; the flesh is melting and tender,

the juice plentiful, sugary, and high-flavoured. It is in eating about the beginning of January, and is esteemed by some as one of the best fruits of the season. In dry and cold seasons this pear is very apt to crack, which greatly diminishes its value.

71. AMBRETTE. *Duham. n. 65. t. 31. Langley Pom. t. 66. f. 4. Pom. Aust. t. 140.* This is a middle-sized pear, roundish, tapering towards the stalk; the skin is whitish on light soils, and grey or russet on strong soils, and changes yellow in ripening; the flesh is a little greenish, fine, and melting, the juice richly sugared and high-flavoured. In good seasons, and favourable soils, the seeds are large, black, and the cells in which they are lodged are very large. It comes into eating about the beginning of January, and is esteemed a very good fruit. It keeps its thorn, and the fruit grows in clusters.

72. EPINE D'HIVER. *Winter Thorn. Duham. n. 64. t. 44. f. 3. Langley Pom. t. 67. f. 6. Pom. Aust. t. 136.* This is of a middle size, rather long than round; the skin smooth, of a pale-green colour, which turns yellow when ripe, and then it is invariably good; the stalk is short and slender; the flesh melting, delicate, and very buttery; the juice is very sweet, and in a dry season, highly perfumed. In moist soils, or in wet seasons, it is very insipid. It succeeds best as a standard, ripens the end of December, and will keep good for two months.

73. ST. GERMAIN. *Duham. n. 96. t. 52. Pom.*

*Aust. t. 146. Poit. et Turp. Fr. t. 89. Hooker Pom. Lond. t. 5.* This is a large long pear, the skin green and roughish, spotted with brown, and has often large russet-coloured spots, particularly near the eye; it turns yellow when ripe; the flesh is white, very buttery, and melting, although not very fine. In dry soils it is stony, but never becomes mealy; the juice is very abundant and excellent, when there is not any sharpness in it. It ripens in the end of December, and will keep till February or March. \*

74. BROWN ST. GERMAIN. This is a very fine high-flavoured pear on dwarfs and standards, and comes in after the Wall St. Germain. It continues in eating from the end of December to the end of March.

75. ST. AUSTIN. *Duham. n. 99. t. 58. f. 3. Pom. Aust. t. 163.* This is a small, long fruit; the skin slightly tinged with red on the side next the sun, and the other turns of a fine bright yellow when ripe. It is sometimes spotted, sprinkled with

\* This pear, owing to the hot and dry summer (1801), has come into eating six weeks sooner this season than I ever remember; and, of course, will be so much sooner out than usual.

This is an excellent bearer, when planted as a dwarf standard, and comes in succession, after the same sort of pears on wall-trees are over.

It is to be observed, that, in dry seasons, fruit should not be suffered to sweat so long in the heaps as directed in the chapter ON GATHERING AND LAYING UP FRUIT; perhaps a fortnight will be long enough.

brown; the flesh is generally hard; the juice is musky, but not plentiful, and often a little sharp. It is in eating the end of December, and will continue good two months.

76. SPANISH BONCHRÉTIEN. *Autumn Bonchrétien. Duham. n. 89. t. 46. Langley Pom. t. 68. f. 2. Pom. Aust. t. 105. Poit. et Turp. Fr. t. 94.* This is a very large pyramidal fruit; the skin is sprinkled all over with small brown dots; it is of a fine lively red or purple colour on the side next the sun, and green on the other, which turns to a pale-yellow when ripe; the flesh is white, with many greenish dots, dry, hard, breaking, or tender and full of juice, according to the seasons and soils; the juice is sweet, sugary, and good flavoured. It ripens the end of December, and will continue good a month or six weeks.

77. BEZY DE CASSOY. *Wilding of Cassoy. Small Winter Butter Pear. Rousselet d'Anjou. Duham. n. 59. t. 29. Pom. Aust. t. 117.* This is a small round pear, a little flattened at the head; the skin is green, yellow when ripe, and entirely covered with brown spots; the flesh is tender and buttery; the juice is very good, and has much of the flavour of the Crasanne, without its roughness. It is in eating in December and January. It is an extraordinary bearer, and commonly produces its fruit in large clusters, if not too much pruned. Miller, in 1731, mentions a tree of this kind at Camden House, near Kensington, which generally produced a great quantity of fruit. It is an excellent bearer

on standards, some of which I have lately grafted, and they are now in full bearing.

78. MARTIN SIRE. *Ronville. Duham. n. 30. t. 19. f. 5. Langley Pom. t. 70. f. 6. Pom. Aust. t. 164.* This is rather larger than the middle size, in shape like the Gros Rousselet; the eye is small and a little hollowed, the middle of the pear is generally more swelled on one side than on the other, but extends equally to the stalk; the skin is smooth, soft, green, but turns yellow when ripe, of a lively red colour next the sun; the flesh is breaking, often with small stones about the kernels; the juice sweet, sugary, and sometimes a little perfumed. It is in eating in January.

79. WINTER ROUSSELET. *Duham. n. 31. t. 19, f. 2. Pom. Aust. t. 153.* This is a small turbinate fruit, the skin greenish on the shaded side, and yellow when ripe; on the side next the sun it is of the same colour of the *Rousselet of Rheims* (brownish red) but a little darker, and when ripe turns more like to the *Martin Sec.* The flesh is partly breaking; the juice plentiful and rather high-flavoured; the skin is apt to contain an austere juice, so that if not pared it is disagreeable to many persons. It is in eating end of January and February.

80. ORANGE D'HIVER. *Duham. n. 29. t. 19. f. 4. Pom. Aust. t. 123. Hort. Soc. Trans. 5. p. 139, t. 2. f. 3.* This is of a middle size, perfectly round, shaped like an orange; the eye prominent and rarely sunk in the head; the skin is very fine, of a brown green, which turns to a rich yellow when

ripe, and sprinkled with very minute brown spots; the flesh is white, fine, breaking, free from grit; the juice very musky and agreeable. It ripens in February, and keeps till April.

81. BEURRÉ RANCE. *Beurré Hardenpont de Printemps. Hort. Soc. Trans. 5. p. 130. t. 2. f. 4.* This somewhat resembles the Colmar in shape, but is longer, and not so blunt at the insertion of the stalk; the eye is large, very little hollowed, stalk long; skin green, never turning yellow, nor partaking of red, sprinkled with many small brown spots; flesh greenish-white, melting, with a little grit at the core; very juicy, sweet, and high-flavoured. It bears well as a standard or against a wall, and the fruit keeps well till March or April.

82. FRANC-REAL. *Golden End of Winter. Duham. n. 60.* This is a large pear, nearly of a globular figure; the skin is greenish, sprinkled with russet-coloured small spots and specks, and turns yellowish when ripe; the flesh is dry and very apt to be stony, but it bakes exceeding well, and continues good from January to March.

83. HOLLAND BERGAMOT. *Amoselle, or Lord Cheney's. Duham. n. 53. t. 25. Pom. Aust. t. 167.* This is very large, of the shape of the Bergamot; the skin in autumn is green, sprinkled with some brown spots. In February and March it turns a bright yellow, and the spots are more visible; the flesh is very good, half breaking, and not subject to be stony; the juice is plentiful, agreeable, and

high-flavoured. This is a good pear, and will keep from end of January to April.

84. BERGAMOTTE DE PÂQUES. *Bergamotte Bugi. Duham. n. 52. t. 24. Langley Pom. t. 66. f. 5. Pom. Aust. t. 120.* This is also called *Easter Bergamot, Terling, Paddington Pear, and Tarquin*. This is a fine handsome fruit, almost round, but a little lengthened towards the stalk; the eye is flat; the skin is pale green, sprinkled with small spots of dark green, and sometimes with a few large brown spots; it turns a little yellow when ripe, and has a small tinge of russet-red on the side next the sun; the flesh is very white, firm, and crisp; the juice plentiful, with rather a sharpish agreeable taste. It comes into eating about the month of April, continues till June, and makes a very handsome appearance at table.\*

85. ROYALE D'HIVER. *Langley Pom. t. 67. f. 4. Duham. n. 71. t. 35. Pom. Aust. t. 130. Poit. et Turp. Fr. t. 118.* This is large, turbinated, broad at the head, the eye small, and deeply hollowed; the skin is smooth and fine, of a beautiful red colour on the side next the sun, yellow on the shaded side, when the fruit is ripe, sometimes sprinkled with brown spots upon the red, and light-brown upon the yellow; the flesh is half buttery, melting, very fine, not gritty, and a little yellowish; the

\* This pear came into eating about six weeks sooner this season (1801) than in any other in my memory.

juice is very sugary in dry and warm soils. It ripens in January and February.

86. MUSCAT L'ALLEMAN. *German Muscat. Duham. n. 72. t. 36. Langley Pom. t. 72. f. 5. Pom. Aust. t. 148.* There is a great resemblance in this to the Royale d'Hiver, but it is less and more pear-shaped; the eye is very small and slightly hollowed; the skin is grey on the shaded side, and red on the sunny side; the flesh is buttery, melting, and a little yellowish; the juice musky and higher flavoured than the Royale d'Hiver. It ripens in March and April, and keeps till May.

87. NAPLES PEAR. *Easter St. Germain. Duham. n. 107. t. 56. Pom. Aust. t. 160.* This is of a middle size, diminishing considerably towards the stalk; the skin is smooth, greenish, turns yellow when ripe, and is slightly tinged with brownish-red on the side next the sun; the flesh is half-breaking, sometimes a little buttery; the juice sweet and agreeable for the season. It is in eating in March.

88. WINTER BONCHRÊTIEN. *Duham. n. 87. t. 45. Langley Pom. t. 68. f. 3. Pom. Aust. t. 129. Poit. et Turp. Fr. t. 114.* This is a very large long pear, generally of a pyramidal shape; the skin very fine, of a bright yellow, inclining to green on the shaded side, and of a flesh-colour on the side next the sun; the flesh is fine and tender, although breaking; the juice tolerably plentiful, sweet, sugary, and even a little perfumed or vinous. It is in eat-

ing from the end of March till June. This is esteemed in France one of the best winter pears, but in England it is seldom so good. It has been observed, if it was grafted on a free stock, and planted in a good soil against a wall exposed to the south-east, and the branches trained at full length, it might be rendered more acceptable than it is at present in England. It succeeds best when grafted on a quince stock, and even in the climate of Paris requires a wall.

89. PASTORALE. *Musette d'Automne. Duham. n. 100. t. 55. Pom. Aust. t. 116. Poit. et Turp. Fr. t. 30.* This is a large long pear, swelling out in the middle; the skin is of a greyish colour, turns yellow as it ripens, and sprinkled with russet spots; the flesh is half-breaking, commonly without any grit; the juice is a little musky, and very good; on a dry soil the juice is very sweet, but on wet soils or in moist years, it has an austere taste. It is in eating in February and March.

90. ST. MARTIAL. *Angélique de Bourdeaux. Duham. n. 88. t. 47. f. 5. Pom. Aust. t. 157.* This fruit is large, in shape and colour like the winter Bonchrétien, but not so large, and a little flatter at the crown; the stalk is very long; the skin smooth, sometimes sprinkled with brown about the eye; on the shaded side it is of a pale yellow, almost white, but the side next the sun is commonly of a fine red colour; the flesh is breaking and tender when quite ripe; the juice very sweet and sugary. It is

in eating in February and March, and will keep very long.

91. CHAUMONTELLE. *Winter Beurré. Duham. n. 78. t. 40. Pom. Aust. t. 143. Poit. et Turp. Fr. t. 56. Hooker Pom. Lond. t. 11.* This is a large fruit, but varies greatly in size and shape, the eye is very deep, and the stalk thick and short; it also varies in colour, sometimes of a yellow colour on the shaded side, and tinged with bright red next the sun; sometimes it is yellow, sprinkled with grey and no red; at other times it is brown like the Crasanne; the flesh is half-buttery, melting, and very good, but often it has some very small stones in it; the juice sugary, high-flavoured, and excellent; its ripening also varies, and will not sometimes keep longer than January, but generally till the end of February. It succeeds best grafted on a quince stock and in a rich light soil, but it will not keep so long as from a free stock.

92. CATILLAC or CADILLAC. *Langley Pom. t. 71. f. 4. Duham. n. 102. t. 58. f. 4. Pom. Aust. t. 162. Poit. et Turp. Fr. t. 74.* This is a very large pear, shaped somewhat like a Quince; the skin is grey, of a pale-yellow colour when ripe, but slightly tinged with brown-red on the side next the sun, entirely sprinkled with small russet spots; the flesh is white, hard, and the juice austere, but it is a very good fruit for baking, and being a plentiful bearer, deserves a place in every good collection of fruit. It will be good from Christmas to April or May.

93. UNION. *Uvedale's St. Germain; Pickering's Langley Pom. t. 71. f. 1. Poit. et Turp. Fr. t. 27.* This is a very large long pear, of a deep-green colour, but sometimes changes to a red next the sun as it ripens. It is not good for eating, but bakes well, and being a great bearer, and a very large fruit, deserves a place in every good collection. It is in season from Christmas to April.

*A Selection of Pears from the Catalogue of Messrs. Anderson, Leslie, and Co. Nurserymen, Edinburgh. — See Dr. Gibson's "Fruit Gardener," 8vo. 1768. p. 296, &c.*

## SUMMER PEARS.

Pear James; soon ripe, soon rotten; has a little flavour, and is the earliest pear that we have in Scotland.

Early Carnock; indifferent, of a yellow colour, and bright red towards the sun; makes a beautiful standard.

Lemon, Lady's Lemon, or Lady Lamont; indifferently good; principally valued for coming early, and being a good bearer.

Green Pear of Pinkey; a small green pear, nearly round, of a sweetish taste.

Forrow Cow, a Clydesdale pear; a large pear with a short stalk; flat towards the eye; its colour red and yellow; its flesh tender and musked.

Pear Sauch, a Clydesdale pear, a big-bellied beautiful pear; the tree large, a great bearer, and fit for an orchard; the pear but indifferent.

Round Winter, a Clydesdale pear; a very ex-

Grey Honey ; pretty good.

Green Orange Pear, or Orange Vert ; a very good pear.

Brute Bone, Chaw Good, or the Pope's Pear ; indifferent.

Golden Knap, supposed Scotch, is a small summer pear, of tolerably good qualities.

Early Achan, an indifferent fruit ; greatly inferior to the winter pear of that name.

Hanging Leaf ; this is its name in Clydesdale ; good and beautiful ; almost round ; its colour red and yellow ; a delicious sweetness is found in its taste.

Scots Bergamot, a large good pear, of a yellow and red colour : its flesh tender and juicy.

Longueville ; very good, but a precarious bearer ; supposed French, but not in their catalogues by that name. (*Caled. Mem.* i. p. 91.)

Musked Bonchrétien, Gratioli, Cucumber, or Spinola's Pear ; a very good pear, if grafted on a free stock ; its pulp is somewhat between short and tender, with a great deal of perfumed juice ; its colour red on one side, and white on the other.

Saffron Pear ; a pretty large well-shaped pear, fit for an orchard.

#### AUTUMN PEARS.

Keather, a Clydesdale pear, of middling size, and oblong shape ; its juice agreeable.

French Carnock ; tolerably good.

Elshin Haft, or Good-Man Pear ; a long pear, flat towards the eye ; its colour green and yellow ; its flesh hard, dry, and sweet.

Drummond, or late Scotch Carnock ; very good, if eaten before it grows mealy ; its colour a bright red and yellow.

Vicar, an oblong pear ; its colour yellow, red and striped ; tender, sweet, and musked, but dry.

Royal Orange Bergamot ; this differs from the Orange Bergamot in being yellower, and sometimes having a faint red on one side.

Green Pear of Yair ; sweet, juicy, and melting ; of a moderate size ; takes its name from Yair, on Tweed-side, where it was first discovered.

Rob Hind ; very indifferent.

Le Besideri ; the wilding of the forest of Heri in Bretagne ; a yellowish pear of middle size ; indifferent.

Unicorn Pear ; of a beautiful red and yellow colour ; but rather austere in taste.

#### WINTER PEARS.

Winter Achan, a Scotch pear ; among the best early winter pears, and equal to most of those of French origin.

Brier Bush, Scotch ; a good pear, and will ripen in most seasons ; it is a small pear, of a firm substance and sweet taste.

Brompton Park ; a seedling sent by Jefferys of that name.

cellent winter pear, as described in Dr. Gibson's "Fruit Gardener," p. 334.

Poir Portrail, or Gate Pear ; for baking.

La Double Fleur, or the Double Flowering Pear ; a large flat beautiful pear, with a smooth skin, and blush colour on one side, and yellow on the other ; the best pear to preserve, taking a beautiful red colour from the fire.

*To those who have small Gardens, and room only for a few Trees, I would recommend the following as the most useful; viz.*

*Summer Pears. Musk Pear; Green Chissel;*

Jargonelle; Summer Bergamot; Summer Bonchrétien.

*Autumn Pears.* Orange Bergamot; Autumn Bergamot; Gansel's Bergamot; Brown Beurré; Doyenné, or St. Michael; and Swan's Egg.

*Winter Pears.* Crasanne; Chaumontelle; St. Germain; Colmar; D'Auch; Eschassery; Winter Bonchrétien; and Bergamot de Pâques.

The above will furnish a regular succession of fruit.

*Of the Management of Pear-trees.*

It will be unnecessary to say much here on the choice of young Pear-trees; as the rules already laid down are sufficient for that purpose.

I would advise those who intend to plant Pear-trees, instead of choosing young ones, to look out for the oldest that they can find in the Nursery, and with strong stems; to have them carefully taken up, with as much of the roots as possible, and carefully planted, after cutting in the roots a little, spreading them as horizontally as you can. Then fill up all round the roots with light dry mould; forcing it in, about those which lie hollow, with a sharp pointed stick; filling the hole up to the top without treading the mould, till you have first filled the hole with as much water as it will contain, leaving it a day or two until the ground has absorbed the water; then throw on some fresh dry mould, and tread it as hard as you can; fill the hole up again with mould to within an inch of the top, and give it a second watering, leaving the

mould about three inches higher than the border, to settle of itself, and to receive the rain that falls, for at least a month. When the mould has become quite dry, you may tread it a second time ; then make a large bason all round the tree, and give it another watering ; then mulch the top over with some rotten leaves or dung, observing to water the trees once a week in dry weather, and sprinkle the tops frequently with a pot, or hand-engine, to keep the wood from shrivelling till the trees have taken fresh root.

When you plant trees against a wall, remember to let the stem stand sloping towards it ; the lower part of it should be six inches from the bottom of the wall, to give the stem room to grow. If planted close to the wall at bottom, the stem, in growing, will be confined on the back, and will grow flat, and be very unsightly. If any roots are in the way, to hinder it from being planted near enough to the wall, they must be cut off : at the same time take care that the tree does not lean to either side, but that, when viewed in front, it may appear perfectly upright. You will sometimes see standards and half-standards planted a foot or two from the wall, which gives them a very disagreeable appearance ; six inches will be quite sufficient. Take care not to wound the stem or root of the tree in planting.

If the young trees have two stems, always remember to cut off one of them, leaving the stoutest and straightest ; observing to plant that side outwards which has most buds on it.

When the buds begin to break well, you may head the trees to three or four eyes, to fill the wall with fine wood. You must never head them afterward, except the leading shoot to fill the wall, observing to leave the foreright shoots to be pruned, as hereafter directed. I have had some trees that had forty pears on them the second year; while some of the same kind bore only eleven pears the fourteenth year after planting, with the common method of pruning.

If you cannot get such old trees as recommended above, get the stoutest and cleanest of the one year's old after grafting.

If any of these trees get stunted after a number of years, you have nothing more to do than to head them as hereafter directed, which will bring them into fresh vigour and fruitfulness.

The method of pruning Pear-trees is very different from that practised for Apple-trees in general. The constant practice has been, to leave great spurs, as big as a man's arm, standing out from the walls, from one foot to eighteen inches and upwards. [*See PLATE VII. Letter C.*] The constant pruning inevitably brings on the canker; and, by the spurs standing out so far from the wall, the blossom and fruit are liable to be much injured by the frost and blighting winds, and thus the sap will not have a free circulation all over the tree. The sap will always find its way first to the extremities of the shoots; and the spurs will only receive in a small proportion, as it returns from the ends of the branches. The fruit stand-

ing at so great a distance from the wall is too much exposed to the weather, and, of course is liable to be hard, spotted, and kernelly ; as *Letter D. PLATE VII.*

I have adopted the following method when the trees were all over cankered, and the fruit small, and not fit to be sent to the table. I cut the tops off as near as possible to where they were grafted ; always observing to cut as close to a joint or bud as possible. The buds are hardly perceptible ; but you can always know where the joints, or forks, are, by the branches breaking out of the side.

Finding the Pear-trees in Kensington Gardens in a very cankerous and unfruitful state, in the years 1784 and 5, I took out the old mould from the borders against the walls, and put in fresh loam in its stead ; at the same time I pruned and nailed the trees in the common way, and left them in that state upwards of eighteen months, to see what effect the fresh mould would have on them ; but, to my great surprize, I found that it had no good effect.

After I had tried the fresh mould as above, I began to consider what was best to be done with so many old pear-trees that were worn out. The fruit that they produced I could not send to His Majesty's table with any credit to myself, it being small, hard, and kernelly. I thought it would be a great reflection on me as a professional man, that, after I had put His Majesty to so great an expence, no advantage was likely to be derived

from it. I saw that some method must be tried to restore these old trees, or that next year they must be grubbed up; and was loth to give them entirely up before I had tried some experiments. I considered, that it must be between twelve and fourteen years before I could have any fruit from young trees; and therefore determined to try an experiment, with a view to recovering the old ones.

I began with cutting down four old and decayed Pear-trees of different kinds, near to the place where they had been grafted: this operation was performed on the 15th of May 1786. Finding that they put forth fine shoots, I headed-down four more on the 20th of June in the same year (for by this time the former had shoots of a foot long), which did equally well, and bore some fruit in the following year. One of the first four that I headed down was a St. Germain, which produced nineteen fine large well-flavoured pears next year, [*See Letter B. PLATE VII.*] and in the third bore more fruit than it did in its former state when it was four times the size.

I left seven trees upon an east wall, treated according to the common method of pruning, which bore the following number of pears upon each tree:—

Epine d'Hiver produced eighty-six pears, and the tree spread fifteen yards.

A Crasanne produced one hundred pears, and the tree spread fourteen yards.

Another Crasanne produced sixteen pears, and the tree spread ten yards.

A Virgouleuse produced one hundred and fifty pears, and the tree spread nine yards.

A Colmar produced one hundred and fifty pears, and the tree spread nine yards.

Another Colmar produced seventy-nine pears, and the tree spread ten yards.

An Eschassery produced sixty pears.

Seven trees headed down and pruned according to my method, leaving the foreright shoots in Summer, bore as follows, in the fourth year after heading.

A Louise-bonne bore four hundred and sixty-three pears, and the tree spread nine yards.

Another Louisbonne bore three hundred and ninety-one pears, and spread eight yards.

A Colmar bore two hundred and thirteen pears, and spread six yards.

A Brown Beurré bore five hundred and three pears.

Another Brown Beurré bore five hundred and fifty pears.

A Crasanne bore five hundred and twenty pears.

A Virgouleuse bore five hundred and eighty pears.

The branches of the four last trees spread nearly in the same proportion as the first three.

A young Beurré, the second year after heading, bore two hundred and thirty pears; and a St. Germain four hundred.

All the above trees stood upon the same aspect and the same wall, and the fruit was numbered in

the same year. A great many pears which dropped from the trees are not reckoned. The trees that were pruned according to the old practice covered at least one-third more wall than the others.

By the above statement it appears, that the trees headed down bore upwards of five times the quantity of fruit that the others did; and it keeps increasing in proportion to the progress of the trees.

On the 20th of June I headed several standards that were almost destroyed by the canker; some of them were so loaded with fruit the following year, that I was obliged to prop the branches, to prevent their being broken down by the weight of it. In the fourth year after these standards were headed down, one of them bore two thousand eight hundred and forty pears. There were three standards on the same border with the above, two of which were St. Germain's; the old tree was of the same kind. One of these trees\*, twenty years old, had five hundred pears on it, which was a great crop for its size; so that there was on the old tree, which had been headed down not quite four years, two thousand three hundred and forty pears more than on the tree of twenty years growth.

When the men numbered the pears, there was near a barrow full of wind-falls at the bottom of the old tree, which were not included.

PLATE VIII. is a correct drawing of an old decayed Beurré Pear-tree, restored from an inch and

\* This tree was about six years old when I planted it fourteen years ago.

a half of bark, which now covers a wall sixteen feet high. In the year 1796, it bore four hundred and fifty fine large pears, and has continued in a flourishing state ever since. The letters *a, a, a*, represent the fruit buds for the present year; *b, b, b*, are those forming for next year; and *c, c, c*, the old footstalks that bore the fruit last year: the small buds are beginning to form, which produce fruit the second year; and *d, d*, are the foreright shoots as they appear before they are cut, which must be at *e*, close to a bud, and sloping towards the wall as much as you can, leaving them as regular as possible all over the tree; you will then have a regular crop of fruit from the stem to the extremities of the branches: but if this be not observed, you will have hardly any fruit next year.

The following is the method which I pursue in training trees that are cut near to the place where they were grafted.

Every year, in the month of March, I shorten the leading shoot to a foot or eighteen inches, according to its strength; this shoot will, if the tree be strong, grow from five to seven feet long in one season; and, if left to nature, would run up without throwing out side-shoots. The reason for thus shortening the leading shoot is, to make it throw out side-shoots; and if it be done close to a bud, it will frequently cover the cut in one season, leaving only a cicatrix, as at *f, f, f*, in Plate VIII. which show every year's growth and cicatrix. When the shoots are very strong, I cut the leading shoot twice in one season; by this method I get two sets.

of side-shoots in one year, which enable me the sooner to cover the wall. The first cutting is performed any time during the Spring, and the second about the middle of June.

When you prune the trees, and cut the fore-right shoots, which should be done in February or March, always cut close to an eye or bud, observing where you see the greatest number of leaves at the lower bud, and cut at them; for at the footstalk of every one of these will be produced a flower-bud. The same will hold good in cutting the superfluous shoots on standard pears. You will have in some sorts of pears, in a favourable season, from five to nine pears in a cluster. This cutting should not be later than March, or the beginning of April, on account of the leading shoot beginning to grow; the next topping, when the leading shoot grows quick enough to admit of it, should be about the middle of June; and the length of the shoots should be according to their strength, having from three eyes, or buds, to six on a side. PLATE VIII. will better explain the different years' growth, &c. than I can do by words. The lowest, *f*, is the place where we began to cut the top off, and *g*, the old decayed stump, with very little bark left.

The canker part beginning to affect the new bark, I cut off all the canker at the bottom last year, and plastered the place with some cow-dung mixed with wood ashes and powder of burnt bones, put into as much urine and soap-suds as would

make it of the consistence of thick paint; this I laid on with a painter's brush. After it had been applied about three hours, I patted it gently down, with my hand, close to the tree. By so doing, I get rid of all the air bubbles that may be under the composition, and make it adhere to the tree, preventing it from being washed off by heavy rains.

In the beginning of August we shorten the fore-right shoots to about four inches long; by this time the shoot will have made its full growth for the season, and will produce fine strong eyes for the following year.

Such shoots as grow near the stem of the tree, if any are wanted to fill up the wall, may be tucked-in as directed for Peaches. [*See also PLATE VIII.*] This will prevent them from looking unsightly, and save them from the fury of the Autumnal and Winter winds.

The tree above-mentioned had a decayed rotten root, the dead part of which I cut all away, till I came to the sound wood. Whenever the trunk is hollow, you must follow it under ground till you have cut out all the decayed parts and rotten roots; otherwise you will lose the tree.

By proceeding according to the foregoing directions, the root will be renewed, while the tree is forming a fine handsome head. In the mean time trench your borders, taking up all the old roots, and add some fresh mould to them, if you can conveniently get it; if you cannot, remove all the sour mould that is about the roots of the trees,

and put in some taken from the border, at a distance from the wall; always remembering to lay the top spit next to the roots of the trees; also, mix some vegetable mould, from the Melon and Cucumber beds, with rotten leaves, as a manure for the borders.

I have headed down many trees that had not this preparation; and yet they throve very well, but did not send forth such fine roots and shoots as those that were so prepared.

If the above directions be followed, you will get more pears in three or four years than you can in twenty-five years by planting young trees, and pruning and managing them in the common way.

If you should find, that, before the pears arrive at half their natural size, they get stunted, after cold blighting winds, and frosty nights (such as we have had for several years past in the months of June and July), I would recommend a new operation to be performed when the weather begins to grow mild.

Take a sharp penknife, and with the point of it make an incision through the rind of the pear from the footstalk to the eye, in the same way as you would scarify a bark-bound tree, taking care to penetrate as little into the flesh of the pear as possible. At the same time beat up some fresh cow-dung with wood-ashes, and with your forefinger rub in a little of this Composition where you made the scarification; as the wound heals, the Composition will be discharged from the fruit;

this will prevent the pears from cracking and bursting, which renders them good for nothing. The sorts that are most liable to this disorder are, the Colmar, Virgouleuse, and Crasanne.

I only recommend this operation for wall-pears. It may be thought by some a troublesome operation. It certainly will take up some time; but sure I am, that no gardener, who wishes to have his master's table well supplied with fine pears during the winter, will grumble at losing a few hours' sleep in the morning, or spending an hour or two in the evening after his men have left work. It may, perhaps, prevent him from spending his money and losing his time in a public-house, or in some trifling amusement to very little purpose. At the same time it will afford him singular satisfaction to find his handywork prosper.

*Respecting the Distance at which Pear-Trees should be planted from each other against Walls, and of the Breadth of the Borders.*

If Pears are grafted on free stocks, such as Colmars, Pear D'Auch, Crasannes, Eschasseries, Virgouleuses, and Winter and Summer Bonchrêtiens, they should be planted at least twelve yards distant from each other, supposing the walls to be from twelve to sixteen feet high; if they are only ten feet, fifteen yards will be little enough.

If Pears are planted on South walls, you may plant Vines, Peaches, Nectarines, or Apricots, be-

tween them, till the trees extend so far as nearly to meet each other: you may then remove the Peaches, Nectarines, &c. to any other situation in the garden where they are wanted. If Pears are planted on West walls, you may plant the same sort of trees between them as on South walls; the fruit on a West aspect will come into use to succeed that on the South. On an East wall, you may plant different sorts of Plums and Cherries between the Pear-trees till they almost meet; then transplant the Plums and Cherries as standards or wall-trees, as you see fit.

The borders for Pear-trees in a large garden should not be less than from ten to twenty feet wide, with a foot-path about three feet from the wall, covered over at top with coal-ashes, or road-sand, to make a dry walk for getting at the trees to cut and nail them, to gather the fruit, &c.

The depth of the mould for Pear-trees should never be less than three feet, laying the best mould at top, to encourage the roots to come as near the surface as possible. If the bottom be clay, it will be very necessary, once in every five or six years, to open the ground round the roots of the trees, and cut off all the large ones that are inclining to run into the clay; by so doing, your trees will throw out fresh roots that will run near the surface, provided the mould is good near the top of the borders.

You may have a crop of early Peas, Lettuce, or Spinach, or any other small crops, on the borders,

during the Winter and Spring ; but no late crops by any means. If the ground can be spared, I would advise to have no Summer crops ; but keep the borders hoed, in particular after rain : otherwise the ground, if a strong loamy or clayey soil, will be apt to crack in dry weather ; but by frequent stirring between wet and dry this will be in a great measure prevented, and the sun's rays admitted into the mould, which will greatly heighten the flavour of the fruit. When you can conveniently spare the borders in Winter, they should be ridged up to sweeten the mould ; which you may very well do, if you sow early Peas on the sides of the ridges ; which is by far the best way to preserve the Peas from the frost, and to prevent them from rotting, which will sometimes happen, if the land be strong, before they begin to vegetate. Or, you may sow an early crop of Carrots or Spinach on the borders.

## CHAPTER VIII.

## OF VINES.

*Different Sorts of Vines cultivated in England. — Of their Propagation. — Experiments on Training and Pruning, with full Directions for the right Performance of both. — Use of the Composition in Pruning. — Of Watering. — Preserving Grapes from Flies, Wasps, and Birds. — Of gathering Grapes, and keeping them in Winter.*

THE Vine is a native of most of the temperate parts of the world, and has been cultivated ever since the flood. It belongs to the first order of Linnæus's fifth Class, Pentandria Monogynia, and is named *Vitis Vinifera*.

I shall here select those Vines which are most esteemed in this country, for the Hot-house, Vinery, and the Natural Wall; and give a short description of each.

*N. B. The letter (h) distinguishes the proper Sorts for a Hot-house; the letter (v) for a Vinery; and the letter (w) for a Common Wall.*

1. JULY GRAPE. *Morillon Noir Hatif. Raisin précocé. Duham. n. 1. Poit. et Turp. Fr. t. 10. Langley Pom. t. 47. f. 3.* This has a small round black berry, growing loose on the bunches, of a

sugary juice ; and is principally esteemed for being early ripe, which is in September. *v. w.*

2. ROYAL MUSCADINE. *D'Arboyce. Langley Pom. p. 114.* This is an excellent grape ; the bunches are large, and divide at the upper part into two smaller bunches or shoulders, and composed of round amber-coloured berries of a rich vinous taste. It ripens well against our walls, and, in a fine season, in September. *h. v.*

3. MALMSEY MUSCADINE. *Malvoise musquée.* This somewhat resembles the preceding ; the juice is very sweet and of a high flavour. This is a good bearer, and a very fine grape. *w. v.*

4. BLACK MUSCADINE. *Black Frankendale. Langley Pom. t. 36.* This is a good bearer, and the berries middle-sized, round, of a fine black colour, and are beautifully powdered with a bluish bloom. *h. v.*

5. COMMON WHITE MUSCADINE. *Amber Muscadine. Chasselas. Langley Pom. t. 35. Duham. n. 2. t. 1.* This resembles the Royal Muscadine. but the berries are smaller : and although it is not so sweet as the Royal, it is the best grape that we have for a common wall, and a great bearer. The berries are round, and when fully ripe are of an amber colour. *w.*

6. WHITE PARSLEY-LEAVED MUSCADINE. *Ciotat. Langley Pom. t. 48. f. 1. Duham. n. 5. t. 2.* This grape has round berries, white, juicy, and sweet. There is a sort of the Parsley-leaved Grape with red fruit. *v.*

7. RED CHASSELAS. *Red Muscadine. Coral. Duham. n. 3.* This is very like the Chasselas Blanc in size and shape; but is of a dark red colour. It is a very good grape, but ripens later than the white.

8. WHITE MUSCAT OF ALEXANDRIA. *Alexandrian Frontinac. Muscat of Jerusalem. Duham. n. 10. t. 5.* The berries are oval, hang loose on bunches, which are long, and not shouldered. This grape has a rich vinous juice, and is esteemed an exceeding good grape for the hot-house. *h.*

9. RED MUSCAT OF ALEXANDRIA. This resembles the former; only the berries are red. *h.*

10. WHITE MUSCAT, from Lunel. This grape has large oval berries, of an amber colour, and full of a vinous juice. This vine is a plentiful bearer, and highly esteemed. *h. v.*

11. BLACK MUSCADEL. This has large oval berries, of a black colour, and pleasant juice. *h.*

12. RED MUSCADEL. This has large red berries of an oval shape, and ripens late. The bunches are very large. *h.*

13. BLACK DAMASCUS. This has large, round, black-coloured berries; the flesh is rich and well-flavoured. This is an excellent late grape. *h.*

14. BLACK TRIPOLI. This has large round black berries, and is an excellent grape. *h.*

15. BLACK SPANISH. *Alicant Grape.* This grape has very large bunches, and also large black berries, of a round shape, a little flat at the end, of a pleasant flavour. *h. v.* It is a very good bearer.

16. **BLACK LISBON.** This grape has large round juicy berries, and the bunches resemble the Black Hamburgh. This is a good grape. *h. v.*

17. **BLACK FRONTINAC.** *Muscat Noir.* *Langley Pom. t. 38.* *Duham. n. 9.* *Poit. et Turp. Fr. t. 130.* This grape has pretty large round berries, loose on the bunches, which are short, black when ripe, and covered with a fine mealy powder. It has a rich vinous juice, and ripens in October. *h. v.*

18. **RED FRONTINAC.** *Muscat Rouge.* *Duham. n. 7. t. 4.* *Poit. et Turp. Fr. t. 18.* This is a very fine grape, and greatly esteemed: it has large round brick-coloured berries; the bunches are longer than the black, and the juice is of a highly vinous flavour. *v.*

19. **WHITE FRONTINAC.** *Muscat Blanc.* *Duham. n. 6. t. 3.* *Langley Pom. t. 37.* *Poit. et Turp. Fr. t. 17.* This has larger bunches than either of the two former, composed of round berries, very closely clustered, with a fine bloom on them, and sometimes a little spotted with brown next the sun. The juice of this grape, when fully ripe, is exquisite. *h. v. w.*

20. **GRIZZLY FRONTINAC.** *Langley Pom. p. 115.* This has round berries, of a colour composed of brown, dark-red, and yellow. \* This grape has an excellent flavour. *h. v.*

\* This was brought into England by Sir William Temple, along with the Arboyce, Red Burgundy, and a Black Muscat, called the Dowager.

21. WHITE SWEET WATER. *Pareyl Druyf. Langley Pom. t. 50.* The berry is large, round, of a white colour, and very agreeable juice. This is esteemed an excellent grape, and ripens in September. *h. v. w.*

22. BLACK SWEET WATER. *Langley Pom. t. 51.* This has a small roundish berry of a sweet taste; but, being apt to crack, is not much in repute. The bunches are short and close. The birds are very fond of this grape, which ripens in September. *v. w.*

23. ESPERIONE. *Turner's Early Black. Langley Pom. t. 45. Hort. Soc. Trans. 3. p. 93. t. 2.* This has large shouldered bunches, the berries vary much in shape, sometimes round, frequently flat-rotund, and indented at the top with the remains of the style; there is often a groove on one or both sides decreasing from the head downward; skin of a deep purple colour, inclining to black, and thickly covered with blue meal; flesh adheres to the skin. It has a pleasant taste, but not high-flavoured or rich. It is very hardy, a great bearer, and ripens its fruit with the Sweet Water and Muscadine. *w.*

24. BLACK HAMBURGH. *Warner's Grape.* The bunches of this grape are large, composed of large oval black berries, of a pleasant sweet juice and vinous flavour. It is a plentiful bearer, and ripens in November. *h. v.*

25. RED HAMBURGH. *Gibraltar.* This has large thin-skinned berries, rather oval, and of a dark-

red, and if fully ripe some of them will turn black. They have a rich vinous flavour, and ripen about the same time with the former. It is an excellent grape, and will ripen on the open walls in good seasons. *h. v.*

26. WHITE HAMBURGH. *Portugal.* This grape has large oval-shaped berries, and is a pretty good bearer. *h.*

27. RAISIN DE CARMES. *Raisin de Cabo. Hooker Pom. Lond. t. 10.* This has long loose bunches, with very large berries of an irregular oval shape; skin thick, of a dusky reddish-purple colour, and covered with a fine meal. Flesh firm, juicy, and rich, but somewhat acid. It grows freely, and bears well. *v. h.*

28. SMALL BLACK CLUSTER. *Black Burgundy. Langley Pom. t. 41.* This has small oval berries, close on the bunches, which are small. The leaves are covered with a hoary down. This is a very pleasant fruit. *v. w.*

29. LARGE BLACK CLUSTER. This is larger than the former, and has a very rough harsh taste. Mr. Speechly says, that he had this grape from Lisbon, and was assured that it is the grape of which they make Red Port Wine. I have had the same grape eight or ten years. *v.*

30. WHITE GRAPE, from Alcobaca. This grape bears large bunches of oval white juicy berries. *v.*

31. WHITE MORILLON. This has an oval-shaped juicy berry. The leaves are downy on the under side. *h. v.*

32. **EARLY WHITE GRAPE**, from Teneriffe. The berries are round, of a middling size, and the flesh remarkably sweet and juicy. *v. w.*

33. **WHITE CORINTH GRAPE.** *White Ascalon. Sultana Raisin. Duham. n. 14. t. 7.* This has a small round berry, with a fine juicy flesh of an agreeable flavour.

34. **BLACK CORINTH.** *Currant Grape. Zante. Black Ascalon. Langley Pom. t. 46. f. 1.* This has a small roundish berry, generally without a stone, of a deep black colour, much clustered on small bunches. It has a sweet juice, and ripens in October. *h. v.*

35. **ALEPPO GRAPE.** This has middle-sized roundish berries, with a juicy flesh of a very fine flavour. This is a curious grape, frequently striped black and white. *h. v.*

36. **RED GRAPE**, from Syracuse. This is a very fine large grape, of a red colour, and irregularly formed oval berries. *h.*

37. **LE CŒUR GRAPE.** *Morocco Grape.* This grape has oval, heart-shaped berries of a tawny colour, and is highly esteemed. *h.*

38. **GOLDEN GALICIAN GRAPE.** This has large oval berries, of a yellow colour, and tolerable flavour. *h.*

39. **BLACK RAISIN GRAPE.** This species has large black berries of an oval form. The skin is thick, and the flesh firm. *h.*

40. **WHITE RAISIN GRAPE.** *Langley Pom. t. 43.* This resembles the preceding; only that the berries are white. *h.*

41. MALVOISE. *Blue Tokay*. This has small brownish berries, nearly oval, powdered with a blue bloom. The juice is vinous. *h. v.*

42. GENUINE TOKAY. This is a white grape, the berries rather oval, with a thin skin, delicate flesh, and agreeable juice. *h. v.*

43. LOMBARDY. *Flame-coloured Tokay*. *Rhenish Grape*. This has fine, large, round, flame-coloured berries, full of a fine juice; and the bunches grow to a great size, frequently weighing more than six pounds. *h. v.*

44. SMYRNA GRAPE. This has a large oval red berry, of a very fine flavour, and is esteemed a very good grape. *h. v.*

45. BRICK GRAPE. *Langley Pom. t. 39*. This is so called from its colour; has small berries nearly oval, of a deep red colour; the skin is thin, and the juice is very sweet. *v. w.*

46. CLARET GRAPE. *Langley Pom. t. 47. f. 2*. This has small black berries, nearly oval, with a blood-red juice; but the grape is very harsh, if not perfectly ripe. The leaves die to a deep red in the Autumn. *h. v.*

47. SYRIAN GRAPE. *Jews*. This has large, white, oval berries, with a thick skin and hard flesh. It is a good bearer. *h.*

48. AUVERNAT. *True Burgundy Grape*. Sometimes called the *Black Morillon*. This is an indifferent fruit for the table; but is esteemed one of the best for making wine. The berries are oval, looser on the bunches than the cluster grape, and

therefore ripen equally. *v. w.* There is also, a White and Grey Auvernat.

49. CAT'S GRAPE. This grape has small oval berries, of a pale green colour. The flesh is soft and juicy, but of a very disagreeable taste, unless quite ripe. *h. v.*

50. DAMSON GRAPE. This has very large oval berries, of a purple colour, growing loosely on large bunches. *h.*

51. ST. PETER'S GRAPE. *Black Grape from Palestine. Langley Pom. p. 115.* This has a large oval berry, of a deep black colour when ripe; the bunches are large, and the flesh juicy; the leaves are very much divided; it ripens late. *v.*

52. GREEK GRAPE. The berries are oval, of a bluish-white colour; and it is esteemed a fine grape. *h. v.*

53. CORNICHON GRAPE. *Duham. n. 12. t. 6.* This has berries of a remarkable shape, long and narrow, of a white colour, with a firm sweet flesh. There is also a variety with black berries. *h.*

54. NEW MUSCAT OF JERUSALEM. This was introduced by Mr. Phillip Miller, a vine of which is now in the Botanic Gardens at Chelsea. It has large round berries of a red colour; some of which I have, in a fine season, seen as large as a gooseberry; but, as it does not ripen well on the natural wall in this country, it might be worth while to try it in a hot-house, or vinery. It was introduced here about thirty-six years ago (1766.) *h. v.*

55. BLACK PRINCE. *Hooker Pom. Lond. t. 45.* This has fine large berries, of an oval, dark black

purple colour, covered with a thick blue meal; the skin is thick, and of rough taste; flesh white, and juice sweet and well flavoured: the bunches grow to a large size; I have had them, in a favourable season, on the natural wall, weigh a pound and a half. This grape very well deserves a place in the hot-house and vinery. It ripens on the natural wall \* in October. Last season (1801) I left some of them on the vines till the middle of November.

*To the foregoing may be added:*

West's St. Peter,

From the Red and White Constantia is made the famous Constantia Wine, so called from a place near the Cape of Good Hope.

My worthy friend, Colonel Paterson\*, informs me, that this vine, when transplanted to but a small distance from that spot, produces a very inferior wine. In his Narrative he says, "Constantia produces excellent wine, though the situation is rather low. It is, however, preferable to all other parts of this district; not only because it is rather more elevated; but on account of the nature of the soil, which is a light sandy loam." p. 5.

\* This gentleman is well known in the literary world, by his "Narrative of four Journies into the country of the Hottentots, and Caffraria;" whence he sent a great many new plants and seeds to England. He also brought home with him some curious skins, and good drawings of many plants, animals, &c.

*Select Vines for a small Garden.*

White Muscadine ; White Sweet Water ; Black Sweet Water ; Large Black Cluster ; Small Black Cluster ; Miller Grape.

St. Peter's, and Black Hamburgh, will do very well in favourable seasons.

*Of the Propagation of Vines.*

The vine is propagated by seeds, cuttings, and layers : and by grafting and inoculation.

When vines are to be raised from seed, it should be sown about the latter end of February, or the beginning of March, in pots filled with light fresh mould, and plunged in a moderately warm hot-bed, gently sprinkling the mould from a watering-pot having a fine rose. About six or eight seeds, if good, will be sufficient for a pot\* of forty or

\* In the vicinity of London, pots are denominated by the number contained in what the potters call a Cast.

They are delivered in at the price of from two shillings and four-pence to half a crown per cast, which contains as under, viz.

The 1st size of 8 in the Cast is called Eights.

|   |    |     |               |
|---|----|-----|---------------|
| 2 | 12 | do. | Twelves.      |
| 8 | 16 | do. | Sixteens.     |
| 4 | 24 | do. | Twenty-fours. |
| 5 | 32 | do. | Thirty-twos.  |
| 6 | 48 | do. | Forty-eights. |
| 7 | 60 | do. | Sixty.        |

Pans for forced Strawberries, French-beans, &c. are also sold by the cast, and at the above price.

sixty to a cast; for, if sown too thick, the plants are apt to be drawn, and thereby become very weak. In dry weather the pots should be watered gently every day: but in wet or moist weather this may frequently be omitted, giving them so much only as will keep the mould moist till the plants begin to vegetate. The proper time for watering is in the afternoon, when the sun is going off the frame. Observe to shut the frame down immediately after watering: and if the heat be not too great, it may remain shut during the night. As the heat of the bed begins to decay, you must add a lining of horse-dung and fresh leaves; which, when occasion requires, may be shaken up and repaired by adding some fresh leaves and dung to it, and thus keep up a proper warmth till the plants have got sufficient strength to do without any bottom heat.

About the latter end of August it will be necessary to take the lights off, that the plants may be hardened before winter, taking care to shelter them in frames covered with mats, which will prevent the frost in the latter end of October and beginning of November from injuring the tender shoots.

When the plants are about six inches high, they should be transplanted singly into deep forty-

---

Pots larger than eights are generally made to order, and paid for according to their size.

There are some smaller than sixties, for seedlings and heaths,

eights, filled with the same sort of vegetable mould as is directed to be used for vines ; taking great care not to hurt the roots, nor to break the leaders : then plunge them again into the hot-bed : but if the heat of the old bed be too much decayed, it will be necessary to have a new one prepared beforehand to receive the pots as soon as the plants are transplanted. If they grow vigorously, it will be necessary to shift them into thirty-twos.

When the plants are above six inches high, they should be carefully tied to small rods, leaving only one stem for the first year. The rods should be as high as the frames will permit.

When the leaves begin to drop, they should be carefully picked off the pots, to prevent the plants from getting mouldy, which would very much injure them.

The plants should be kept under frames, or put into the green-house, in hard winters, to shelter them from severe frosts. In the spring, about March or the beginning of April, if from seed ripened in this country, they may be planted out against the walls where they are to remain ; but if from seed imported from vine countries, I would advise not to plant above one or two against the wall, or in the hot-house, before you have obtained a specimen of the fruit, and be satisfied that they are worth cultivating.

After they are planted, they should be cut at the third eye, if strong ; but at the second, if

weakly : at the same time remember to rub off the lower bud with your finger and thumb, as hereafter directed.

If vines are to be propagated from cuttings, they should be chosen from the shoots that are best ripened, and have the shortest joints ; always having one or two joints of the last year's wood, cutting it perfectly smooth and a little rounding at the lower end, and as near to a joint of the old wood as possible. The upper end should also be cut smooth and sloping towards the wall ; but if they are planted in beds or borders, let the cut always face towards the North. When cuttings are planted against piers or walls, let it be at about a foot distant from each other, according to the vacant space, and so deep as to have the second eye level with the ground ; remembering always to rub off the lower eye. By so doing, if no accident happens to the top bud, there will be a shoot produced from each eye, with a little one under, which should always be rubbed off as soon as it begins to swell ; for, if suffered to grow to any considerable size, you will be in danger of injuring the large one in rubbing the small one off. Remember also to pick off all the runners and side-shoots, as before directed, leaving only two shoots, which should be trained at their full length. About January or February they may be pruned, leaving one or two eyes on each according to the strength of the shoot, which should be managed as shall be more fully explained hereafter.

In the first year, especially if the summer be dry, and proper attention be not paid to the watering of them, they will make but little progress; but in the second year you will plainly discern which is the strongest plant, which only should be left to fill up the vacant space on the wall; the rest should be taken up and planted in other situations where they are wanted.

Mr. Speechly and others practise a method of propagating the vine from one eye, and a few inches of the preceding year's wood, which he prefers to those raised by cuttings in the common way, for the following reasons: "They have more abundant roots, grow shorter jointed, are more prolific, and will, if permitted, come into bearing the second year."

You should make choice of the cuttings after a warm dry season such as last year (1800); but not after such as the year before, when the wood did not ripen properly, owing to the wet and cold season. Each cutting should have two inches of the old wood, with one eye of the new. When you prune your vines, you will have great choice; you should then select your cuttings of a middling size, the wood round and perfectly ripened. Pots are to be filled with rich light mould that has been well meliorated and prepared some time before. The cuttings are then to be prepared for planting, as follows. The bottom part should be cut perfectly smooth: and if any of the old dead snags remain, they should be cut off

close to the quick wood, and the top cut sloping towards the back of the hot-house or frame when placed in them. I would recommend planting only one cutting in each pot, which as to size should be a deep forty-eight; by that means the plants will grow much stronger and quicker than when many are crowded together, and the sun and air will have a freer admission to ripen the wood; for, when many are planted in one pot, they shade one another, and in a considerable degree prevent the sun and air from passing freely among them. When the plants begin to get strong, and the pots full of roots, it will be necessary to shift them from the forty-eights to the thirty-twos.

The above mode is best adapted for private gardens, but for nurserymen, &c. who raise plants for sale, and cannot conveniently spare so much room, it may be necessary to plant three or more cuttings in each pot.

The same rules for watering, transplanting, shifting, &c. are to be observed here as for seedlings.

A method very frequently practised by nurserymen and gardeners, when they wish to have their plants fit for sale the same year, is to plant them in pots; and place them in the hot-house, among the tan, or the flues, or round the curbs of the pit. I saw this method practised last year, with great success, by Messrs. Lee and Kennedy, in their hot-house at the vineyard, Hammersmith.

They may be raised in this manner, either planting them singly in small pots, or several in a pot, according to its size, transplanting them separately when they have taken root. In proceeding thus, it will be necessary to have a hot-bed ready, to plunge the pots in as soon as they are transplanted. By this means you will forward their growth very much, and before autumn have them fit for sale.

Vines are also propagated by layers in the following manner.

They may be propagated by stools in the open quarters, in the same manner as nurserymen propagate forest-trees and shrubs; but the best way is to take layers from walls or palings, observing to train the shoots at full length during the summer. Then, about the month of February, take some of the finest and strongest shoots, and lay them across the footpath into pots (twenty-fours or sixteens) filled with fresh mould, and plunged in the ground about two inches below the surface; at the same time making an incision or two in the old wood, or giving it a twist just below a joint: they will generally take without notching or twisting: yet, as it is the surer way, I would advise it to be done. (Introducing the shoots through the bottom of the pots is now laid aside, as the layers generally have, when this method is followed, larger roots below than in the pots.) The layers should then be cut, leaving two or three strong eyes upon each.

When the shoots begin to run, they should be tied to long stakes, to prevent their being broken by the wind. All the runners and side-shoots are to be picked off, leaving only two or three fine strong shoots on each plant, which should be trained at full length during the summer.

After the shoots are laid, it will be necessary to mulch them with good rotten dung, or rotten leaves, which will keep the mould moist; and in very dry summers, such as the last (1800), it will be necessary to give them a good watering once or twice a week: this will wash in the dung or leaves about the roots, and cause the layers to shoot more vigorously.

By this method of laying, you may have two or three rows of layers from one wall: taking care to lay the branches alternately, and to keep the pots plunged about two inches below the level of the ground.

In choosing vines from the nursery, I would recommend those which have the strongest and longest shoots.

If the foregoing directions are properly attended to, the plants will be well rooted in the pots before autumn, and fit for planting in vineries, hot-houses, &c.

When any are to be planted out, they should be carefully cut off from the mother vine, and carried in the pots to where they are intended to be planted; taking care to preserve the ball as

much as possible when they are turned out of the pots.

If the season be warm and fine, the grapes of early kinds ripen very well on these layers before they are taken up; and, if properly managed, they will bear some fruit the first year after planting. One of the strongest shoots must be left nearly at full length, cutting it as high as the uppermost full bud, leaving nothing but round well-ripened wood. If there are three shoots, the remaining two should be cut so as to leave only two full eyes upon each, which should be trained at full length, as before directed, to produce fine wood for next year. The shoot which was trained the preceding year should then be cut down, leaving only two strong eyes to produce wood for the following year; and so on every year, cutting the branches alternately; by so doing, you will be able to keep your walls always covered with fine healthy bearing wood. Thus a great deal of time is saved in furnishing hot-houses, vineries, &c.

This method of laying is practised with great success by many nurserymen in the neighbourhood of London; in particular by Messrs. Gray and Wear at Brompton-park nursery, and by Messrs. Kirke at Brompton; each of whom raises annually several hundred plants, for which they find a great demand.

If any vines that have been raised from seed should not prove to be of a good flavour, they will be very fit to graft or inarch the finer sorts of vines

on: as the coarser sorts grow more vigorous than the finer, they are for that reason fitter for grafting or inarching.

The best manure for vines is a mixture of vegetable mould \*, rotten spit-dung, and fresh loam (turf and all); this should be thrown in a heap, and frequently turned, for a year or two, before it is used.

*Observations and Experiments on the Training and Pruning of Vines.*

The following is the method that I pursued with some vines which were planted against the piers of a south wall, and among old peaches, nectarines, plums, &c.

When I took them in hand, the fruit was so small and hard as to render it unfit to be sent to the table. The vines were trained upright, which caused them to grow so luxuriantly that the sap flowed into the branches instead of the fruit.

In the year 1789, I let two strong branches grow to their full length without topping them in the Summer. In 1790, I trained them in a serpentine form (See PLATE X.), leaving about thirty eyes on each shoot, which produced one hundred and twenty fine bunches of grapes, weighing from one pound to a pound and a quarter each. Every one that saw them, said that the large ones were as fine as forced grapes; while the small ones

\* For producing vegetable mould, see p. 145.

produced from branches of the same vine, trained and pruned in the old way, were bad natural grapes, and not above twice the size of large currants.

More fully to prove the success attending this experiment, I next year trained five plants in the same way, allowing the shoots intended for bearing wood to run to their full length in summer, training them wherever there was a vacancy between the old trees; where there was none, I ran them along the top of the wall, without topping them. In Winter I trained them in a serpentine manner, so as to fill the wall as regularly as possible: they were as productive as those in the former year.

After a three years trial, I thought I was warranted to follow the same practice with the whole; and in the year 1793, I sent, for the use of His Majesty and the Royal Family, three hundred and seventy-eight baskets of Grapes, each weighing about three pounds, without planting a single Vine more than there were the preceding year, in which I was able to send only fifty-six baskets of the same weight: and those so bad and ill-ripened that I was ashamed of them, as they were not fit to be sent to the table.

In this year there was more than a quarter of the crop destroyed by birds and insects, and rotted by the wet.

Although the above statement is within the bounds of truth, it may appear to the reader like an exaggeration; but it is in the power of every

one, who will follow the directions here given, to prove the advantage that will accrue from this method of training.

The above experiments were all made on the natural walls, and I hope will be sufficient to convince every unprejudiced person of the great advantage that the serpentine method of training Vines possesses above the common way.

It may be proper to observe, that the shoots should be brought as near as possible from the bottom of the Vine, that the wall may be well covered. When the walls are high, and the shoots from the serpentine branches strong, we sometimes let them remain; but if the walls are low, and the serpentine branches produce weak shoots, we cut them out in the autumnal pruning, and train up the strongest of the young wood in their room; as directed in the explanation of PLATE X.

*Of the Pruning, and Training of Vines.*

It is to be observed, that the wood must be strong, or the Vines will produce small bunches. If that be the case, cut them down to two or three eyes, in order to have strong wood for next year. Vines bear their fruit on the wood that was produced the preceding year. If there be a great deal of old naked wood on them, as generally is the case with some small weak shoots at the extremities, always cut them down as near to the ground as possible; you will then have no fruit

for that year. Or you may cut every other shoot, leaving the old ones to produce some small Grapes. The next year you will have plenty of fine wood, provided you take care to nail in the strongest shoots, and pick off all the side shoots that are produced from the eyes, pinching them off with the finger and thumb, or cutting them out with a sharp penknife close to the bud or eye; but never twist them, for by twisting them, you will hurt the bud that produces the Grapes next year; always observing to cut as near to a bud as possible, and taking care to lay in the wood very thin in Summer, that the sun and air may be freely admitted to ripen it: by these means it will grow very strong. Take care also to keep the shoots nailed to the wall, which will prevent their being broken by the high winds; observing to pick off all the side-shoots every time you nail them, which ought to be done several times during the Summer months, according to the quickness of their growth. In fine weather they will grow so very quick, that you will have occasion to look over them once every fortnight or three weeks, if you wish to have them in good order. Never suffer the Vines to run together in a cluster and to mat, which will infallibly ruin them for bearing the succeeding year. Top the shoots that have been trained in a serpentine manner, as soon as the Grapes come to the size of very small Green Peas, a joint or two above the fruit; but never top the

leading shoot, nor that which you intend should bear fruit next year.

I shall now give some directions for the second year's pruning.

I would never recommend the pruning of Vines till the beginning of February, except in such a season as the present; for they are more forward now (in the middle of January) than they were last year in the latter end of March: this is owing to the fine Autumn and mild Winter, and the wood being so well ripened in the preceding Summer. It is, however, very common with some to begin pruning soon after the fall of the leaf, before the wood becomes hard; but if a frost sets in before the wood is hard, in particular after wet Summers and Autumns, it will be very much injured; I have frequently seen it almost killed after autumnal pruning. We often have fine weather in the months of October, November, and December, with sun and drying winds, which helps to ripen the wood after wet Autumns.

When the Vine-leaves begin to fall, remember always to take a soft broom and sweep them off upwards in a gentle manner, which will be of great service in assisting to harden the wood.

When you begin to prune in February, always make choice of the strongest and longest shoots, leaving them as long as you find the eyes good and plump, and the wood round; but by no means leave them when they become flat; as in that case they seldom bear fruit; and if they do, it will be

very small. I never lay in any that has less than fifteen, and from that to thirty good eyes, according to the strength of the shoot, which will produce two bunches from every good eye. I have had seventy bunches of grapes from one shoot. The shoots that have borne fruit in the preceding year should be cut out next year, except when you want to fill the wall, and the shoots are very strong. You will always get plenty of fine healthy young wood, if you are careful when you prune in the Winter; therefore never leave any but fine strong wood, always cutting at the second, third, or fourth eye; remembering to rub the lowest bud off, and that which comes out at the joint between the new and last year's wood. By these means you will get as much fruit from these short shoots as you would have by the common way of pruning. You must always observe to leave two or three of the strongest shoots for next year's bearing wood, and never top them. If you have not room to train them, you may lead them over the tops of the other trees, if the Vines are planted against Piers; or you may run them behind the standards, if there be any, which is generally the case when the walls are high; thus you will cover all the wall, which will have a very beautiful appearance when the fruit is ripe, besides furnishing a plentiful supply of fine Grapes for the table. You may run the shoots at the bottom of the wall behind the dwarf trees, or you may tack them down over the top of the wall on the other side, provided the

walls are low. I have had very fine Grapes on East and West walls, in good seasons, between Peaches, Plums, &c. particularly when the trees are young. You must keep cutting in the Vines as the other trees grow and fill up the walls. I also train them over the tops of trees on each side; which never does any harm to the trees below, provided you keep them nailed to the wall. I have also planted Vines between trees on North and East aspects, and trained them over the tops of the South and West walls, to fill the upper parts, till the Peaches and Nectarines cover them. I then cut away part of the Vines, leaving only as many shoots as I may think necessary.

Two years ago I removed some old Apricots that covered a wall about one hundred and sixty-five feet long, and planted them against a new wall, leaving five Vines that were planted against the piers. These five plants have, in the course of two years, covered the above wall from top to bottom, and bear plenty of fine Grapes every year. I also moved an old Vine on the wall near to the above, and cut it in pretty close; it has in three years spread twenty-six yards, and bears very fine fruit.

Against one of the piers had been planted a black Hamburgh Grape, and at the other side of the same pier was planted a Muscadine, at the distance of about two feet from each other; I pruned them both according to my method, and,

the second year after, they produced one thousand one hundred bunches of fine Grapes.

I also tried an experiment by taking some shoots from a South wall, opening the ground deep enough to lay them in across the footpath at the distance of about four feet from the wall, and tied them to stakes, training them as Espaliers, laying-in the wood as directed for walls, and keeping them as low as possible, that they might not shade the bottom of the wall; I also pruned them as I do those against walls, laying the shoots in very long, except those that were intended to bear fruit next year, from which I took off all the side shoots and runners against the walls and Espaliers. In a favourable season these bear very fine fruit, better than what is got from the walls by the old method of pruning.

Always observe to use the Composition as soon after pruning as possible. As the Vine is very porous, it soon imbibes the wet and moisture, which brings it quickly to decay.

If at any time a Vine should be cut late in the season, it will be apt to bleed much; in that case, the powder must be applied, repeating the application till the bleeding stops.

I cut two strong Vine-branches in the month of June and three more in July, in very hot weather, on purpose to try the effect of the powder in stopping the bleeding. The sap rose so strong that it worked out at the top in a froth; I ap-

plied the powder, which in a short time entirely stopped it.

Although the foregoing directions and observations are chiefly for Vines on the natural wall, I have recommended the same method to be practised for forced Grapes.

*I shall now give some Directions for the Watering of Vines.*

After the Grapes are set and begin to swell, you may water them with the Barrow-Engine, sprinkling them all over the leaves and fruit, pressing your fore finger over the top of the pipe; by doing this you can throw the water as fine as small rain, which will wash all the dust off the vines and leaves, that are frequently covered with it, especially if the garden be near a public road, as is the case at Kensington. You should also wash the insects off the trees.

In fine weather I sprinkle all the wall-trees three times a week, which keeps them clear from insects, and promotes the swelling of the fruit; but this operation must never be performed when the nights are cold and frosty. You should begin to sprinkle the trees when the sun is in an oblique direction, or gone off the wall, which may be about four o'clock on a South aspect; by doing it at this time, the leaves will have time to dry before night, and so prevent the frost, if there should be any in the night, from injuring them. In very hot and dry weather, give the trees a good bottom

watering once a week, which will forward the swelling of the fruit. Vines require a great deal of watering; but when the fruit is fully swelled, you should leave it off; particularly when the nights begin to get cold, as it would hurt the flavour of the fruit.

We shall say something in this place respecting the preservation of Grapes from flies, wasps, and birds; but for full directions on that head, see the Chapter ON INSECTS, &c.

As soon as the large fly makes its appearance, you must provide plenty of bottles a little more than half filled with some sweet liquor to entice the flies to enter them, where they will be drowned. You must hang the bottles on the nails at proper distances all over the Vines, and also place some of them at the bottom of the walls. The blue fly comes much earlier than the wasp, and you will find it no less destructive to the fruit. It will therefore be necessary to hang up the bottles betimes, in order to destroy as many of them as possible before the wasp makes its appearance, and have the bottles ready for this second enemy.

When the Grapes begin to ripen, you will be troubled with other enemies; the birds will now begin to attack the fruit; it will then be necessary to bag some of your fine handsome bunches, but to bag them all would be an endless job, if you have a full crop and a large garden. I have had five men bagging for three weeks, and yet could not bag the half of what were on one wall.

Where the bunches are very thick, the quickest way is to cover the trees with nets, or buntine, (a kind of stuff of which ships' colours are made), which will admit a free air to the Grapes, and will dry soon after rain. They will also be a good covering for the trees in the Spring, in cold, wet, or snowy weather. Always observe, that the bunches of Grapes should be kept under the shade of the leaves till they begin to ripen; then you may begin to pick off the leaves which cover the fruit, (leaving those a little above it to be a shelter from the wet and frost in the nights); this will assist the ripening of the fruit; and take off only a few leaves at a time, according to the quantity of Grapes to be gathered at once: by these means your fruit will continue three times as long in succession as it would if the leaves were picked off all at one time.

I have often seen all the leaves taken off from the fruit soon after it was set, which prevents it from swelling, and the fruit will become hard and small, and will generally crack.

When the leaves are not too thick, they admit the rays of the sun to pass through, and a warm glow of heat will be reflected from the wall.

You may find it convenient to let the grapes hang as long on the walls as you can; I have often let them hang till the middle of November, only covering them with nets, or buntine.

When the frost begins to set in sharp, you

should then gather the Grapes. Where there are several bunches in one branch you may cut it off, leaving about six inches in length, or more, of the wood, according to the distance between the bunches, and a little on the outside of the fruit at each end; seal both ends with some common sealing-wax, such as wine-merchants use for sealing their bottles with, which you may buy at the wax-chandler's; then hang them across a line in a dry room, taking care to clip out, with a pair of scissors, any of the berries that begin to decay or become mouldy, which if left would taint the others. In this way I have kept Grapes till the sixth of February; but, if they are cut before the bunches are too ripe, they may be kept much longer.

Having plenty of Grapes in the Winter makes a great addition for the table; and, if properly kept, they will be of a much finer flavour than the Portugal Grapes, which are generally at a very high price during the Winter and Spring.

Grapes may also be kept by packing them in jars (every bunch being first wrapped up in soft paper), and covering every layer with bran, which should be well dried before it is used, laying a little of it in the bottom of the jar; then a layer of Grapes, and so on, a layer of bran and of Grapes alternately, till you have filled the jar; then shake it gently, and fill it to the top with bran, laying some paper over it, and covering the

top with a bladder tied firmly on to exclude the air; then put on the top or cover of the jar, observing that it fits as close as possible. These jars should be kept in a room where you can have a fire in wet or damp weather.

## CHAP. IX.

## OF FIGS.

*Different Sorts described. — Of Raising, Pruning, Training, and Sheltering Fig-Trees.*

THE Fig has been cultivated in England ever since the year 1548. *Turner's Names of Herbes, Sign. Dij.* Some of the oldest that we know of in this kingdom are in the Archbishop of Canterbury's gardens at Lambeth.

This genus of plants is arranged in the third order of Linnæus's twenty-third class, entitled Polygamia Dioecia, and is named *Ficus Carica*.

*The following are the Sorts best worth cultivating in this Country.*

1. BROWN CHESNUT-COLOURED ISCHIA. This is one of the largest that we have: it is of a brown or chesnut.colour on the outside, and purple within; the grains are large, and the pulp sweet and high-flavoured. It ripens in August; and if planted against a hot wall, two crops may be obtained annually.

2. BLACK ISCHIA FIG. This is a short middle-sized fruit, flat at the top; the skin is almost black when ripe, and the inside of a deep red. The flesh is high-flavoured, and the trees good bearers.

3. **GREEN ISCHIA FIG.** This is an oblong fruit, nearly globular at the top, with a green skin; but, being thin, is stained through of a brownish cast by the pulp when full ripe. The inside is purple, and the flesh high-flavoured. It is ripe about the middle of September.

4. **SMALL BROWN ISCHIA FIG.** This is a small pyramidal fruit; the skin of a light-brown; the flesh of a purple cast, and of high flavour. It ripens in October.

5. **YELLOW ISCHIA FIG.** This is a large fruit, the skin yellow, and the flesh purple and well-flavoured. It ripens in October.

6. **SMALL WHITE EARLY FIG.** *Langley Pom. t. 52.* This is a roundish fruit, flat at the top, with a very short foot-stalk; the skin is of a pale yellow when ripe: the flesh is white and sweet. It is ripe about the latter end of August, or beginning of September.

7. **BLACK GENOA FIG.** This is a long fruit, broad at the top, but slender at the stalk, of a dark-purple colour, nearly black, with a meal over it, the inside of a bright red, and the flesh very high-flavoured. It ripens in the latter end of August.

8. **LARGE WHITE GENOA FIG.** *Poit. et Turp. Fr. t. 4.* This is a large globular fruit, lengthened to the stalk; the skin is thin and yellow when ripe, and red within. It is a good fruit, and is ripe about the latter end of August. This and the preceding bear two crops annually.

9. **BROWN and BLACK SMALL ITALIAN FIGS.** These are cultivated in pots; the fruit is small, round, and very delicious. I have gathered from one plant in a twenty-four pot, two dozen of Figs at one gathering.

10. **MALTA FIG.** This is a small brown Fig, compressed at the top and pinched in towards the stalk; the skin of a pale-brown, the inside of the same colour; the flesh is sweet and high-flavoured. It is ripe in August and September.

11. **MURREY. *Brown Naples Fig.*** This is a pretty large globular fruit, of a light-brown colour, with some faint marks of dirty white, and the inside nearly of the same colour; the flesh is well-flavoured; and it ripens about the middle of September.

12. **LONG BROWN NAPLES FIG.** This is a long fruit, compressed at the top, with long footstalks. The skin of this fruit is of a dark-brown when ripe, the flesh inclining to red; it has large grains and a good flavour, and ripens about the beginning of October.

13. **MADONNA. *Brunswick. Hanover Fig.*** This is a large long pyramidal fruit; the skin brown, the flesh a lighter brown, coarse, and has but little flavour. It ripens about the middle of September.

14. **COMMON BLUE or PURPLE FIG. *Duham. n. 3. tab. 2. f. 1.*** This is a large oblong fruit, ripens in August, and is a good bearer.

15. **GENTILE FIG.** This is of a middle size;

oval fruit, the skin yellow, and the flesh inclining to the same colour. It has large grains, and a good flavour; ripens very late, and the trees are but indifferent bearers.

*There are also the following, viz.*

|                                                 |                       |
|-------------------------------------------------|-----------------------|
| Best Early White.                               | Marseilles.           |
| Black Provence.                                 | Milward.              |
| Cyprian.                                        | Small Black Ischia.   |
| Ford's Seedling.                                | White Ischia. Same as |
| Green Naples.                                   | Yellow Ischia.        |
| Large Black.                                    | Yellow Cæsar.         |
| Large Blue. Same as com-<br>mon Blue or Purple. | Vernisingue.          |

*Figs proper for a small Garden.*

Large White Genoa; Early White; Murrey Fig; Small Brown Ischia, and Black Ischia.

In a good season, the Brown or Chesnut-coloured Ischia, the Black Genoa, the Small White Early, the Murrey, or Brown Naples, and the Common Blue, or Purple Fig, will ripen on standards.

Figs are raised from suckers, layers, or cuttings, and will thrive in almost any soil, but do not like a wet bottom; they generally produce more fruit on a strong loamy soil than on a dry one. Layers, or cuttings, are preferable to suckers.

*Observations, &c. on Pruning Figs.*

They should never be pruned in Autumn or during the Winter: the best time is at the latter

end of April or beginning of May; by that time you will see what shoots have been killed by the frost in Winter. The end of those branches more particularly will be hurt where the wood has not ripened well in Autumn: they should be cut into the sound wood, and as near to an eye as possible. When the branches have been suffered to run up leaving the bottom quite naked, you should cut out every other branch as near to the ground as you can, which will furnish the wall with fine young wood: observing to stop the ends of the shoots in the beginning of June; this will cause them to throw out side-shoots, which will bear fruit the next Summer. By that time you will have plenty of fine wood; you may then cut down the rest of the old branches that were left the preceding year, observing to prune them about the same time as you pruned last year: always remember to pinch off the ends of the strongest shoots except the leading ones, at the top bud.

When you prune in the Spring, never shorten the shoots, as the fruit is produced near the tops. There will be a great many fine short side and foreright shoots, which should never be cut off but when they are decayed. These shoots will ripen much better than the long strong ones, and will not be so liable to be killed by the frost in Winter. By following this method, you will have the trees covered with fruit from the top to the bottom of the walls, instead of having a few fruit

only at the top, which is the case when the common method of pruning is practised.

When the Figs are about the size of small nutmegs, you should pinch off the point of the top bud with your finger and thumb, or cut it with a sharp penknife ; and always remember to use the powder, wherever you cut or pinch, to stop the oozing of the milk, which, if suffered, would greatly exhaust and injure the trees.

Take care not to lay in the branches too thick ; they should be from a foot to eighteen inches distant.

The trees must be covered in the beginning of Winter, before the frost sets in, otherwise the ends of the shoots will be hurt by the first sharp frost, before the wood is ripened and hardened, which will oblige you to cut them as before. When Fig-trees are very much injured in hard Winters, the best way will be to cut as near the ground as possible ; and the second year you may get them into a fine bearing state, if you manage them as above directed.

I shall now give some directions as to the best method of covering them.

I generally cover them with bentings, or short grass, from the pleasure-ground ; which I find answers the purpose very well : after it is thoroughly dry, it may be put in a cock, covering it with straw, to prevent the rain from penetrating into it, which will cause it to heat and rot ; or it may be put into one of the sheds. If you cannot

procure grass, get some dry moss. First cover the trees with laurel, yew, fir, or spruce-fir boughs, and then tuck in the short grass or moss among the branches, beginning at the top of the tree, tucking in the grass, &c. as you descend, till you come to the bottom. Fern, when well dried, makes an excellent covering. You may thatch the tree on the outside with the long leaves of the common fern; when you can get these, there will be no occasion for short grass. Fern, when it can be procured, which it may in most country places, will be found preferable to laurel.

Figs may also be sheltered in Winter by wrapping hay or straw-bands round the branches of the trees; then open the ground, lay in the branches, and cover them over with mould about nine inches deep, leaving the ends of the shoots about three inches out of the ground, and covering the ground over with some rotten leaves, or old tan, &c. to keep out the frost: you may also cover the roots of the trees in the same manner.

If the walls are low, and the borders broad, you may bring all the branches front ways; but when the walls are high, you can only bring the side-branches forward in the above manner.

Some cover with reeds and straw; the latter I by no means approve of, as it is very apt to harbour rats and mice, on account of some of the grain being left in it.

Be careful to observe, when you put on the grass, that no mice, &c. have got amongst it; and

examine, during the Winter, that no rats or mice get among the branches of the trees that are covered against the walls; if they do, they will infallibly bark the branches, and in that case you will be under the necessity of heading the trees down.

I would recommend setting traps, such as shall be described hereafter, near the roots of the trees, as soon as they are covered.

Take care not to uncover the Figs too soon in the Spring; and it should be done partially, as frequently there are frosts and cutting winds in the months of April and May, which will infallibly kill the young fruit as they make their appearance in the Spring.

Those branches which have been laid into the ground should be taken up in the month of April, taking off the hay and straw bands, and then nailed to the wall. Stick in among the branches some fern-leaves, or any other light covering, to protect them from the drying winds and frosts, till the fruit comes to the size of a large walnut, or rather till the leaves are sufficiently large to protect the fruit.

The Italians, when they wish to forward the ripening of Figs, drop in a little sweet oil, from a quill, into the eye of the fruit; but care must be taken not to hurt the skin, which would make the Fig burst. This will make a difference at least of a fortnight in the ripening.

As soon as the leaves begin to fall, brush them off

with a broom, but by no means till they will come off easily. If they are forced off before they begin to wither and decay, the trees will bleed at the footstalks. At the same time you should clear the stalks of all the small late fruit, which, if suffered to remain during the Winter, will rot, and injure the tree so as to prevent it from bearing the ensuing Summer. If you observe any milk oozing from the footstalks, use a little of the Composition, which will stop it, and heal the injured part. By doing this, you will assist the ripening and hardening of the wood before the Winter frosts set in.

When you plant fig-trees, let them be from twenty to twenty-four feet apart, and train them horizontally, which will render them much more fruitful than when they are trained upright, which causes them to run up in long naked wood.

Observe also to leave spurs, or short shoots, all over the branches; and when the buds begin to swell, all the short shoots should be pinched, as before directed.

As the branches of standard Fig-trees are very liable to be killed in severe Winters, it will be necessary to lay them also in the ground, wrapping them up in hay or straw-bands, as before directed for wall-trees. It will be sometimes impracticable to lay down the middle branches; they must, therefore, be well covered with hay or straw-bands, and the outside ones laid down, going regularly

round the tree, and taking particular care not to hurt them with the spade ; then mulch them with rotten leaves, &c.

After hard Winters, I have frequently been obliged to cut Fig-trees down very near to the ground, and apply the Composition : in the course of two years the new wood has covered over the old stump, and the branches filled up the former space, bearing also plenty of fine fruit.

In a plentiful year, when there are more than you want for the supply of the table, the remainder may be dried for Winter use.

## CHAPTER X.

## OF QUINCES.

*The best Sort for the Kitchen Garden.—Of their Propagation, Planting, and Pruning.—Of Bark-bound Trees, and of those which have rough Bark.*

THE Quince is called *Cydonia Malus*, from Cydon, a town in Crete famous for this fruit, whence it is said to have been originally brought.

It belongs to the fourth Order of the twelfth Class of the Sexual System, *Icosandria Pentagynia*. Linnæus has joined it to the Apple and Pear, and named it *Pyrus Cydonia*.

This is a very beautiful tree when in flower, and when the fruit is ripe in Autumn. It was cultivated in this country in Gerarde's time, 1597, but probably much earlier. It is mentioned by Tusser in 1573. *Husband. fol. 32.*

There are three varieties of this fruit:

1. The Oblong, or Pear-shaped Quince. *Knoop fruct. p. 10. t. 1.*
2. The Apple-shaped. *Knoop fruct. p. 10. t. 1.*
3. The Portugal. *Langley Pom. t. 73. f. 2.*  
and 3. *Poit. et Turp. Fr. tab. 16.*

The best sort for planting in the Kitchen Garden is the Portugal, being the fittest for baking or

stewing, It is of a fine purple colour when dressed, and is much better for Marmalade than any of the other sorts. The oblong or Pear kind and the Apple Quince are also planted in fruit-gardens; and there are several other sorts cultivated in the nurseries about town, and planted in shrubberies for variety and ornament. The Portugal sort is very useful to mix with Apples for making pies and puddings; for, when the Apples are flat, and have lost their flavour, they add a quickness to them.

*Of the Propagation and Pruning of Quince Trees.*

They are easily raised by layers, or by cuttings taken from the tree in March. They should be planted in a shady place, in rows at about a foot distance from each other, and about three inches from plant to plant in the rows. Mulch them with rotten leaves, or rotten dung, which will keep the ground about them moist; and water them frequently in hot weather. About Michaelmas those that are well-rooted may be planted out, and those that are not should remain another year. They may also be propagated by budding or grafting; and these trees will bear sooner, and be more fruitful, than those raised by any other method.

The Quince tree may be pruned much in the same way as you would prune an Apple-tree, taking care to cut out all the old diseased and dead wood, and the cross branches in the middle of the tree, which are apt to injure each other by

friction. In general you will find old trees much hurt by injudicious pruning: in that case, you must head them down, cut out all the cankered parts, and also all the diseased and dead wood where the tree is hollow, or where large branches have been cut or broken off; applying the Composition as for Apple-trees.

Quince trees are very apt to have rough bark, and to be bark-bound: in that case, it will be necessary to shave off the rough bark with a draw-knife, and to scarify them when bark-bound; then brush them over with the Composition, as hereafter directed.

I would, however, advise to plant Quince trees at a proper distance from Apples and Pears, as bees and the wind might mix the Farina, and occasion the Apples or Pears to degenerate.

## CHAPTER XI.

## OF MEDLARS.

*Different Sorts.—Their Propagation and Manner of Treatment.*

THE Medlar is ranged in the fourth Order of Linnaeus's twelfth Class, Icosandria Pentagynia; and is named *Mespilus Germanica*.

*The different Sorts cultivated in this Country are,*

1. The Common, or narrow-leaved Dutch Medlar. *Pom. Franc. 2. p. 45. tab. 2.*

2. The German, or broad-leaved Dutch Medlar. *Pom. Franc. 2. p. 45. tab. 3. Poit. et Turp. Fr. tab. 31.*

The latter, being the largest fruit, is generally cultivated in England. There is a smaller sort, which is a variety of that called the German, or broad-leaved Dutch Medlar; the fruit is small; and the tree is more frequently planted in pleasure-grounds than gardens.

There is another variety called the Nottingham Medlar, which is very much esteemed by some for its sharp and poignant taste.

The Oriental, or Quince-leaved sort, (*Mespilus Tomentosa*,) according to Mr. Philip Miller, is called the Dwarf Cherry of Mount Ida, in Crete, where the shepherds feed upon the fruit. The

fruit is large, roundish, and of a fine red colour when ripe.

There are several species of *Mespilus* (*Pyrus*, Willd.) now growing in the gardens of this country, that have been introduced from North America, which are very ornamental in pleasure-grounds and parks, and to whose fruit the deer and birds are very partial.

They are raised from seed, or by grafting; those who wish to keep the sorts true should propagate them by grafting on their own stock.

The Medlar requires much the same sort of treatment as the Quince-tree. Cut out all the dead and cankered wood; and, when they begin to get stunted, head them down, and apply the Composition, as directed for Apple-trees.

Medlars should hang upon the tree till they begin to rot, as those who are fond of this fruit never eat it till the pulp is quite soft. It may be proper to observe here, that those who wish to have their Medlars large and fine, must keep the tree thin of wood.

As many people are fond of the fruit of the Medlar, I would recommend planting some trees of the large Dutch sort in the kitchen garden; the other sorts may be planted in pleasure-grounds and parks.

Medlars, as well as Quinces, should be planted at a proper distance from Apple and Pear-trees.

## CHAPTER XII.

## OF GOOSEBERRIES.

*Different Sorts of Gooseberries ; and the Weight of many large new ones from Manchester. — The Propagation, Planting, and Pruning of Gooseberries. — A Method of destroying Caterpillars.*

**T**HE Gooseberry, and Currant, are ranged by Linnæus under one Genus, in the first Order of his fifth Class, Pentandria Monogynia, the former is named *Ribes Grossularia*.

*The Gooseberries cultivated in this Country are,*

| <i>Red.</i>              | <i>Yellow.</i>         |
|--------------------------|------------------------|
| Hairy.                   | Great Oval.            |
| Smooth.                  | Great Amber.           |
| Deep Red.                | Hairy Amber.           |
| Small Early Red.         | Large Smooth.          |
| Damson, or Dark Red.     | Large Rough.           |
| Red Raspberry.           | Large Tawney, or Great |
| Early Black-red.         | Mogul.                 |
| Champaigne.              |                        |
| Wilmot's Early Red.      |                        |
| <i>Hooker Pom. Lond.</i> | <i>White.</i>          |
| <i>tab. 25.</i>          |                        |
| <i>Green.</i>            | <i>Common.</i>         |
| Hairy.                   | Large White-veined.    |
| Smooth.                  | Large Crystal.         |
| Gascoigne.               |                        |

*A List of the largest new Sorts shown in Lancashire last Summer (1800,) with the Colour and Weight, communicated by Messrs. M'Niven, Nurserymen, Manchester.*

*Red Gooseberries.*

October 27. 1800.

In favourable seasons many of the above sorts have been known to weigh more by several penny-weights.

tween the rows, and four feet from plant to plant ; or you may plant them round the edges of the quarters, about three feet from the path ; you will then have the ground clear for cropping, and a man, by setting one foot on the border, can gather the Gooseberries without injuring the crop.

As Gooseberries love a rich soil, they should be dunged every year, or at least have a good coat of dung once in two years.

Never plant them under the shade of other trees, as it will injure the flavour of the fruit.

#### *Of Pruning Gooseberry-bushes.*

It is a practice too common in pruning Gooseberries, to let them branch out with great naked stems, suffering them to remain in that state for years. When that is the case, they should be cut down near to the ground in the Winter pruning ; this will make them throw out fine strong healthy shoots, which will bear fruit the second year. Gooseberry-bushes, in general, bear their fruit on the second year's wood. Care should be taken in Summer to keep the middle of the bush clear, to admit a free air into them ; leaving the finest and strongest shoots from six to ten inches distant from each other. This will help to ripen and harden the wood. It is a practice with some to shorten the shoots in the Autumn or winter pruning ; this should be always near to a wood-bud ; which may be known by its being single, whereas fruit-buds

are in clusters. The shoots may be shortened to eight or ten inches, according to their strength. Some leave them at full length for three or four years, thinning out those that are superfluous. Always leave a proper number to be trained up between the full length shoots, to succeed them when they are tired of bearing; then cut the old ones down to the young ones that are to succeed them. By these means you will always keep the bushes in a constant state of bearing.

You may observe, that those branches which were cut the first year, will in the second throw out short dugs, or spurs, which produce the fruit; and these should by no means be cut off, unless the branches are in a sickly state, and require to be cut close down (as is the case this year 1800), when the bushes are over-loaded with fruit. It will then be necessary to cut out a good deal of the old wood, to assist Nature to recover herself after producing so great a quantity of fruit. This year the bushes are so loaded that the branches are bent down to the ground.

Gooseberries are well worth paying attention to, as they supply the table so amply till the wall fruit comes in.

There have been considerable additions made to them, of late years, from the great attention that has been paid, by the gardeners and others of Manchester and its neighbourhood, to raising Gooseberries from seed.

Their Catalogues now contain between four and

five hundred sorts or varieties; but some are so near each other as hardly to be distinguished. By mixing up a rich soil to plant those in which have been raised from seed, and by watering, shading, and thinning the fruit, they have grown to a size much larger than any that had ever been seen in this country. They have made it their principal study to improve this valuable fruit, and have given great encouragement, by establishing societies for distributing prizes annually to those who raise the largest and finest new sorts. But it must be allowed, that some of the largest are much thicker in the skin, and not so well-flavoured as some of the old sorts.

I enquired of Messrs. M'Niven, Nurserymen at Manchester, how many good and distinct sorts they could send me out of their numerous Catalogue; they told me, that they could send about eighteen or twenty sorts, which they could answer for being good and distinct. I accordingly gave an order, and received all the sorts that they could warrant good, which turned out to my satisfaction.

Great attention should be paid to the cultivation of the early and late sorts. In some old gardens, in particular, there are very valuable sorts that have been of late too much neglected; I would therefore recommend to those who live in the neighbourhood of such gardens, to observe their time of ripening, and to cultivate those especially which are early and late.

It is a practice with some to clip the tops of Gooseberries with a pair of garden shears, as they would clip a thorn hedge; this I by no means approve of, as the fruit will not be half the size, nor of so fine a flavour, as when the bushes are kept clear of superfluous wood.

Care should be taken in Spring and Summer to stock, or grub up, all the suckers from the roots of the bushes, leaving their stems clear and uncumbered.

Many of the Lancashire sorts are apt to grow horizontally, and the branches frequently trail on the ground, which renders them liable to be broken by high winds, especially when they are loaded with fruit. In that case I would recommend two or three hoops to be put round them, to which the branches may be tied, to support them, and prevent their being broken by the wind.

Those who wish to have their Gooseberries very late should plant on North walls and palings, between the other trees, and they may be removed when the trees begin to meet. If laid in thin, they will bear very fine and handsome fruit. I would advise to plant the finest late sorts; as by this method the table will be supplied much longer than by the common custom of planting in quarters.

Immediately after pruning, I always apply the Composition to the ends of the shoots and cuttings; and I find it of great use in preventing the exhalation of the sap, and preserving the cuttings till they take root.

Gooseberries are very much infested with a small green caterpillar, which frequently devours both leaves and fruit.

You must, therefore, be very attentive, and observe their first appearance on the bushes; for, if not destroyed early, they will increase so fast, that they will soon devour all the leaves, and the fruit will then be good for nothing. They make their first appearance generally on the edges, and undersides of the leaves.

Take some sifted quick-lime and lay it under the bushes; but do not at first let any of it touch the branches or leaves; then shake each bush suddenly and smartly, and the caterpillars will fall into the lime; if the bush be not shaken suddenly, the caterpillars on being a little disturbed, will take so firm a hold as not easily to be shaken off. After this is done, sift some of the lime over the bushes; this will drive down those which may have lodged on the branches. The caterpillars ought to be swept up next day, and the bushes well washed with clear lime-water mixed with urine; this will destroy any caterpillars that may still remain, and also the Aphides, if there are any on the bushes.

## CHAPTER XIII.

## OF CURRANTS.

*Different Sorts of Currants. — Propagation, Planting, and Pruning of them. — How to preserve them from Insects.*

CURRANTS, (with Gooseberries,) are arranged by Linnæus in the first Order of his fifth Class, Pentandria Monogynia, and are named *Ribes rubrum*, and *Ribes nigrum*.

The sorts most commonly cultivated in this country are, the Red and White Dutch Currants, and the common Black, and American Black Currants.

*The following Sorts are also cultivated by the Nurserymen about Town, and in other Parts of England, viz.*

|                                 |                               |
|---------------------------------|-------------------------------|
| Common Red.                     | Long-bunched Red.             |
| Champagne, large Pale and Red.  | Striped-leaved Red.           |
|                                 | White Crystal. <i>Pearl</i> . |
| Fine new White Dutch.           | Large Pale and Red            |
| <i>Hooker Pom. Lond. t. 36.</i> | Dutch.                        |

The Currant is the most useful of all the small fruit, either for the table and kitchen, or for preserving, making wine, &c. and continues longer in succession than any other. With proper management, Currants will continue in use from June to

November. Black Currants are very much esteemed by some ; yet they are seldom sent to the table, but are very useful for making jelly, frequently taken for sore throats, colds, &c. \*

*On the Propagation of Currants.*

Currants may be raised from seed, layers, &c. When the trees are cut low, you may lay down some of the branches either in Winter or Spring, when the ground in the quarters or rows is dug, which should always be done annually. In the Autumn following, these layers will have made fine roots ; you may then plant them out where you wish them to stand, and they will bear fine fruit in the following summer.

Currants may also be propagated by cuttings, as Gooseberries ; always remembering to make choice of the strongest and straightest shoots.

\* In Ireland, Black Currants are frequently steeped in whisky, of which they make punch, and recommend it as a good medicine for coughs and colds. I once had two gallons of it sent me by a friend for that purpose ; some of it was taken in a glass of warm water by a person who was very much afflicted with a severe cough, and thought to be in a decline, which effected a perfect cure in three or four nights.

The Currants, for this purpose, should be bruised and put in a jar, and the whisky poured over them : let it stand for a week or fortnight, covering it close down ; then strain it through a fine cloth or sieve, and put it in bottles or casks for use. Currants may be used in this manner with brandy, gin, or any other spirits. They may also be preserved as Cherries, and sent up to table.

Under the bushes that have been covered for late fruit, you will always find plenty of self-sown plants, which I would advise you to plant out by themselves. Those who make Currant-wine may save the seed, after the fruit is squeezed, and dry it: it may then be sown in Autumn, or early in the Spring, on a bed of fine light earth; by which you will, most probably, obtain some fine varieties. By no means propagate them from suckers, as they never grow handsome, and are very liable to throw out a great many suckers.

In many gardens there still remains a small sort of Red and White Currant not worth cultivating; I would therefore advise those who have any of them in their gardens to root them up, and plant, in their room, the large Red and White Dutch, the long-bunched Red, and Champagne large Pale Red. Currants may be planted out in the same manner as Gooseberries, either in quarters or in single rows round the edges of quarters.

I would particularly recommend planting a few against a South or West wall, or paling, which will produce fruit much earlier than in quarters, &c. Also to plant some between other fruit-trees on North walls, or palings, for latter crops; these may be covered with double nets, to preserve them from birds; tucking in a few fern branches between the two nets, which will prevent the heat of the sun and drying winds from shriveling the fruit. In quarters they should be covered with mats for the same purpose; at the same time permitting all

the leaves to remain on the bushes, to shade the fruit and make it keep the longer,

*Pruning of Currant-Bushes.*

The pruning of Currants is nearly similar to that of Gooseberries. You may begin in the month of November, and continue till March, as it suits your convenience.

Currants should never be left too thick of wood ; and a great deal depends on the management of them in Summer, to have strong and fine wood for the following season. If they have been neglected for some years, and suffered to run up to long naked wood, they must be cut down near the ground ; they will then set forth fine strong shoots. In this case, I would recommend heading down every other tree, and cutting the others partially, by taking out every other branch as near as can be to the ground, unless they are trained up with single stems, in which case it will be necessary to cut them as near as possible to where the branches begin to break out and form the head.

In the Winter pruning, you must preserve the strongest and finest shoots, leaving them from nine to eighteen inches long, according to their strength, and from eight to ten inches apart, and as regular as possible from top to bottom of the tree ; taking care to cut out all the dead and weak shoots. Pay particular attention in Summer, and keep the middle of the bush open to admit the sun and air ;

preserving the finest and strongest shoots that are nearest the stem. Some are fond of training them up with single stems, to a considerable height, to form fine round heads, which are very ornamental, if not suffered to run up too high; as in that case they are liable to be broken by the wind, if not well supported by stakes. Care must be taken not to let the shoots run to more than six inches long; because such short shoots will not be so liable to be damaged by the wind as long and weak ones are, especially when loaded with fruit. I prefer dwarfs from three to four feet high.

The same manner of pruning, &c. will do for Black Currants; but, as they grow stronger than the Red or White, the shoots should be left thinner, and laid in longer, which will make them produce larger and finer fruit.

Those against walls and palings should have the shoots laid in thinner than those in the quarters, and trained as horizontally as possible, shortening them in the Winter, pruning to a foot or eighteen inches, according to the strength of the shoots.

As Currants are very liable to be devoured by earwigs, which take shelter under their leaves and branches, bundles of bean-stalks should be hung up some time before the bushes are covered with mats or nets. If proper attention be not paid to this, the fruit will generally suffer very much from these insects. After the bushes are covered, take the mats off once in three or four days, and kill the earwigs that have got into the bean-stalks, which it

will be necessary still to keep hung up. As there is a sweetness in the inside of bean-stalks which attracts the earwigs, they very readily take shelter in them from rain.

By paying proper attention to the foregoing directions, you will be able to keep these destructive insects under, and preserve the greater part of the fruit.

Be particularly careful to stock up all suckers at the roots of the trees, and keep them as clean as possible ; otherwise the suckers will prevent the sun and air from penetrating to the roots, and greatly weaken the trees.

What has been said above, will, I hope, be sufficient to direct those who are fond of cultivating this valuable and useful fruit.

Currants are very liable to be infested with Aphides and other insects, which shall be taken notice of in another place.

## CHAPTER XIV.

## OF RASPBERRIES.

*Different Sorts of Raspberries; and of Propagating, Planting, Watering, Staking, and Pruning them.*

**RASPBERRIES** are a very useful fruit for the table, for preserving, for making of jam, sauce, &c., and continue a long time in bearing.

The Raspberry belongs to the fifth Order of Linnæus's twelfth Class, Icosandria Polygynia; and is a native of England. It is named *Rubus Idæus*.

*The following are the Sorts cultivated in this Country.*

|                       |                                 |
|-----------------------|---------------------------------|
| Early White:          | Large Yellow Antwerp,           |
| Double Bearing White. | <i>Hooker Pom. Lond. t. 37.</i> |
| Large Common White.   | Smooth Cane Double-             |
| Large Red.            | bearing.                        |
| Large Red Antwerp.    | Woodward's New Rasp-            |
|                       | berry.                          |

*Of Propagating, Planting, and Pruning Raspberries.*

Raspberries are raised from suckers and layers.

They should be planted in a piece of ground by themselves, and (except the Early White) at the

distance of about six feet from row to row, and four feet in the rows.

The ground should first be well trenched and dunged before the Raspberries are planted. Make choice of the strongest and finest plants that come out from the sides of the stools, where they have been standing for some years; or encourage the strongest plants that come out betwixt the rows after digging, which should be done annually. In digging the ground, you will frequently happen to cut the roots with the spade, which will occasion a great number of small plants to come up; of these select the strongest and finest, and hoe up all the superfluous ones. But I prefer laying down some of the strongest outside shoots in the month of March; as by the following Autumn they will make fine roots, and may be planted out in a quarter or piece of ground where you intend them to remain. These will not be so liable to throw out suckers as those which are produced from suckers.

When you plant out fresh pieces of Raspberries, it should be done in moist weather, as the roots are very delicate, and liable to be hurt when exposed to a dry air. If, however, they are planted in dry weather, take care to moisten the roots with water, and cover them with wet litter, or leaves, during the time of planting.

In planting, open a trench with the spade along the line where the suckers or layers are to be planted: cut off all the small fibry roots with a

knife, leaving only the stronger roots : put them into the trench, and cover them with some earth ; then water them well, and throw the remainder of the earth over them, letting them remain till you have finished planting the piece ; then, where you first began to plant, begin and tread the ground with your foot as hard as you can along each of the trenches, and in the same direction as you planted ; then with a spade level all the ground smooth, and run it over with a rake, taking off any stones and rubbish that may be left on the surface.

In dry weather, the plants should be watered two or three times a week till they have taken root. It will be necessary to stake the Antwerp and other strong-growing sorts, with stout stakes ; then run a couple of small rails at top, to tie the branches to ; which will prevent their being broken by the wind, or beaten down by the rain. The Early White and smaller sorts may be planted together at top, tying them round with the small yellow willow, which will keep them together. Some of the Early Raspberries may be planted between the trees on a West aspect, to produce early fruit before those in the quarters come in. The Antwerp will thrive exceedingly well against North walls or palings, and will produce late crops. Such as are planted against walls or palings should be tacked to them.

Where you find any of the small Red and White Raspberries, destroy them, and plant the following

sorts in their room, viz. the Large Red, the Smooth Cane Double-bearing, the Large Red and White Antwerps, the Large Common White, the Double-bearing White, and Woodward's New Raspberry.

Some prefer pruning Raspberries in Autumn, a practice which I by no means approve. As they bear the fruit on the wood of the preceding year, they are very liable to be killed by the frost in severe winters; but, by deferring the pruning till the month of February, you will have great choice of fine wood for bearing the following Summer: remembering to root out, or cut down, all the wood that bore fruit the preceding year, which generally dies; selecting only from five to seven of the most vigorous and strong shoots from the last year's wood, to bear fruit the ensuing season. These shoots may be pruned to the length of three or four feet, according to their strength, if they are of the Smooth Cane Double-bearing sort (which generally bears a second crop in Autumn, and will in fine seasons continue bearing from June to November); but if the large Antwerp, the shoots should be left five or six feet long.

The Early White, which never grows so strong as the above sorts, should be shortened to two feet and a half, or three feet. These should be planted in rows about three feet distant from each other, and two feet from plant to plant in the rows; always remembering to keep them clear of suckers, and to cut out the dead, or last year's

wood, as before directed ; making choice of the strongest shoots for bearing wood. But be careful not to cut off the little spurs on the sides, which bear the fruit.

Raspberries will continue in bearing five or six years ; by which time you should have a fresh plantation to succeed them. The young plants will bear some fruit the first year, and come into full bearing the second year after planting. If they be suffered to remain more than five or six years on the same ground, they will degenerate, and bear small fruit. Care should be taken not to leave above eight or ten of the strongest shoots, rubbing off or pulling up all the superfluous ones ; and to keep the ground well hoed and clear of weeds between the rows.

## CHAPTER XV.

## OF BARBERRIES.

*The Different Sorts, and their Culture.*

THE Barberry is useful for preserving and pickling, and for garnishing of dishes; the trees also have a fine effect in shrubberies and pleasure grounds, being beautiful flowering shrubs. In Autumn and Winter they have a delightful appearance, from the various coloured fruit. I would therefore recommend planting them in all shrubberies and pleasure grounds. Those who are fond of the natural harmony of singing-birds, will find Barberries well adapted for attracting them to the spots where they are planted, most birds being very fond of them. They should not, however, be planted near the sides of public walks, as the flowers emit a very strong and rather disagreeable smell.

The Barberry is ranged, by Linnæus, in the first Order of his sixth Class, entitled Hexandria Monogynia; and named *Berberis Vulgaris*.

*The following Sorts are most esteemed for their Fruit, viz.*

1. RED BARBERRY without stones, which has an agreeable flavour when full ripe.

2. WHITE BARBERRY. *Poit. et Turp. Fr. t. 52.*
3. BLACK SWEET; which is the tenderest of them, and should be planted in a warm situation.
4. COMMON RED with stones. *Duham. 1. p. 152. et tab. Poit. et Turp. Fr. t. 51.* This is planted more for ornament than use, on account of its beautiful red berries.
5. PURPLE FRUITED. *Poit. et Turp. Fr. t. 59.*  
The Barberry is a native of England.

*Of Raising and Pruning Barberries.*

Barberries are very easily propagated from suckers and layers, and require the same management in pruning as other flowering shrubs. I would always recommend planting them in pleasure grounds, and not in kitchen gardens. On grass lawns, in pleasure grounds of small extent, they have a fine appearance, and are frequently planted in such situations as ornamental flowering shrubs; they are also planted frequently in clumps.

When you wish to increase them, encourage the finest and cleanest shoots in Summer, by trimming all the side branches off thin; and when you dress the shrubberies in Winter, lay down the strong shoots, which will take root, and be fit to transplant in Autumn following. When designed for use, they should be trained up as standards and half-standards, and they will grow from six to twelve feet high. In Summer, trim off all the straggling

and superfluous shoots ; so as that they may make fine handsome heads.

Barberries may also be raised from seed ; but suckers and layers are best for preserving the sorts distinct.

The Red Barberry, *without stones*, seldom proves correct, when the trees are young.

## CHAPTER XVI.

## OF MULBERRIES.

*Different Sorts cultivated in England. — Propagating, Planting, and Pruning of them. — Of Restoring old and decayed Trees.*

THE Mulberry is a native of Persia ; whence it was introduced into the Southern parts of Europe, and is now commonly cultivated in England, Germany, and other countries where the Winters are not very severe. It is ranked in the fourth Order of Linnæus's twenty-first Class, Monœcia Tetrandria, and named *Morus*.

We are informed, that Mulberries were first cultivated in this country in 1597 ; but I have reason to believe, that they were brought hither prior to that period, as many old trees are to be seen standing at this day about ancient monasteries and abbeys ; from which it is at least probable, that they had been introduced before the dissolution of those houses.

Four large Mulberry-trees are still standing on the site of an old kitchen-garden, now part of the pleasure-ground at Sion House, which, perhaps, may have stood there ever since that house was a monastery. The late Duke of Northumberland

has been heard to say, that these trees were about three hundred years old.

At the Priory near Stanmore, Middlesex, (the seat of the Marquis of Abercorn,) there are also some ancient Mulberry trees. The Priory was formerly a religious house.

In a very old garden at Chelsea, which belonged to the late John Browning, Esq. (who was a very good botanist, and had a large collection of trees and plants), there is one of the largest Mulberry trees that I ever saw, and which appears to be extremely old.

*Those commonly cultivated in this country are :*

1. COMMON BLACK MULBERRY TREE. *Morus Nigra*, Linn. *Pom. Aust. t. 67. Poit. et Turp. Fr. t. 20.* This is much esteemed for its delicate fruit. It is now common in most parts of Europe, except where the winters are very severe. There is a variety of this with jagged leaves, and smaller fruit; but Mr. Miller says, that it is a distinct species, a native of Sicily; and that the fruit has no flavour; consequently it is not worth cultivating. There were some of these trees in the Botanic Garden at Chelsea. *Cult. before 1548. Turner's Names of Herbes. Sign Ev.*

2. WHITE MULBERRY, *Morus Alba*, Linn. *Pom. Aust. t. 68.* This tree is raised in great abundance in Italy, and other Southern countries, for the

leaves to feed silk-worms \* ; though it is said that the Persians generally use the Common Black Mulberry for that purpose ; and this latter is the only sort raised for the sake of its fruit, which is very wholesome. *Cult. before 1597. Gerarde's Herb. 1325,*

3. RED, OR VIRGINIAN, MULBERRY TREE. *Morus Rubra, Linn. Pom. Aust. tab. 69. Poit. et Turp. Fr. tab. 69.* This grows to a considerable height, and bears dark reddish berries. *Cult. 1629. Park. Paradis. p. 596. n. 3.*

The two last are cultivated in this country, only for the sake of variety.

Mulberries are raised from seed, or propagated from cuttings and layers.

Those raised from seed have frequently male flowers, and produce no fruit ; these, therefore, should never be made choice of for fruit-bearing trees, unless they have been seen to bear in the nursery.

The best bearing branches of old trees are to be chosen for cuttings and layers ; for some branches of these trees produce only katkins, and trees raised from them will never produce fruit. If they are to be raised from layers, they will generally take root sufficiently the first year to bear separating from

\* This tree possesses the peculiar property of breeding no vermin, either while growing or when cut down ; neither does it harbour any caterpillar, the silk-worm excepted. *Evelyn's Sylva, by Hunter, vol. ii. p. 40. Edit. 1786.*

the parent tree, and should then be planted in a nursery, and trained up with single stems. In four years they will be fit to plant out where they are to remain. They should be planted at a proper distance to admit the sun and air, as the fruit, when the trees are too close, is very apt to turn mouldy; they should also be sheltered from the East, North, and West winds.

But the best way of raising Mulberries is from cuttings of the former year's shoots, having one joint of the two-years' wood. Plant them out in Autumn, if fine weather, or in the month of March, in rows nine inches apart, and at the distance of two inches in the rows, leaving only two or three buds above ground: mulch the ground with leaves or dung well rotted, to keep it moist, and the plants will require little watering. If they succeed well, they may, next season, be transplanted into a nursery, and treated as directed for layers. These young trees, while they remain in the nursery, should be transplanted every three or four years.

I would recommend planting of Mulberries in grass orchards and pleasure-grounds, because the finest of the fruit, when ripe, frequently drops, which, if it fall on dug or ploughed ground, will be soiled and rendered unfit for use, as the earth will adhere so to the fruit as to render the cleansing of it impracticable; but if planted on lawns, or in grass orchards, the fruit can be picked up without receiving any injury. Another reason for

planting these trees on lawns or in orchards is, that, when full grown, they are too large for a kitchen-garden. The soil in which they thrive best is a rich, light, and deep earth.

As the fruit is produced on the young wood, you should cut out only such branches as cross others, and such as are decayed, or broken by any accident; at the same time apply the Composition. If, however, the heads should become too full of wood, it will be necessary to thin them, as the fruit is larger and better flavoured where the heads are kept thin of wood.

I have found many of these trees in a very decayed state, with the trunks quite hollow; and have tried the efficacy of the Composition on several of them, cutting out all the dead wood and cankerous parts of some, and heading-down others that were stunted and sickly. After these operations they put forth vigorous branches, and bore excellent crops of fruit, more than double the size of that which they produced in their former state.

I would advise those, who have any old decayed Mulberry trees, to treat them in the same manner; but those which are very much decayed should be headed-down; this will throw them into a healthy bearing state, and in two or three years they will produce plenty of fine fruit.

In the lawn in front of the house of John Grove, Esq. at Little Chelsea, there are four old Mulberry trees, which a few years ago were so very much decayed, and so full of wounds and dead wood,

that they produced very little fruit, and that of a small size. I had all the decayed and rotten wood carefully cut out, and the branches trimmed, and then the Composition applied. In the first season they sent forth fine shoots, and in the second produced plenty of fruit, of a better flavour, and double the size of that which they formerly bore.

As old Mulberry trees produce, not only a greater quantity of fruit, but also much larger, and of a finer flavour than young ones, it is well worth while to take some pains to repair the injuries which they may have sustained by accidents or age.

I am sorry to say, that this pleasant and valuable fruit is but very little cultivated in this country. \*

\* Gerarde, in his description of the Mulberry tree, has the following curious paragraph:—“Hegesander in Atheneus affirmeth, that the Mulberry trees in his time did not bring forth fruit in twenty years together; and that so great a plague of the gout reigned and raged so generally, as not only men, but boys, wenches, eunuchs, and women, were troubled with that disease.” P. 1325. edit, 1597.

## CHAPTER XVII.

## OF THE SERVICE.

*The Cultivated Service, the Mountain Service, and the Maple-leaved Service; with their Culture.*

**T**HERE are three sorts of the Service tree cultivated in England, viz. the Cultivated Service, the Mountain Service, or Mountain Ash, and the Maple leaved Service. The first is a native of the warmer climes of Europe and England; and the other two also grow wild in different parts of England.

The Service belongs to the twelfth Class of Linnæus's System, entitled Icosandria Trigynia.

*Of the Cultivated or True Service, (Sorbus Domestica, Linn.)  
Eng. Bot. t. 350.*

This tree is well worth cultivating, both for its fruit and for ornament. It is beautiful in the month of June when in flower, and the fruit in Autumn has a fine appearance, and grows to a large size if the trees be kept thin, and not overladen with wood. They may be planted in orchards among other fruit-trees; for as they flower much later than Apples and Pears, there will be no danger of the farina intermixing with theirs. They may also have a place in plantations in the pleasure-ground, or singly on the lawn, or in rows by

the sides of gravel-walks : in this case, they should be trained with straight stems eight or ten feet high, and all the straggling branches should be cut-in, to assist them in forming handsome round heads. These trees may be intermixed with thorns, and will have a very good effect.

We have only two sorts cultivated in the garden ; viz. the Apple-shaped, and the Pear-shaped Service tree.

These trees are propagated from seed, layers, and cuttings. By raising them from seed you may perhaps obtain several varieties ; but the best method of preserving the sorts, when you have fine varieties, is by grafting or budding.

Train the stem, if for standards, six or eight feet high ; but if for dwarfs, about three feet high ; which latter may be planted in shrubberies. The fruit, when ripe, may be gathered and put in the fruit-room, letting it remain till nearly in a state of decay ; it will make a variety when served up to table among the Autumn fruits.

The wood of this tree is very useful for making picture-frames, toys, &c.

When the trees are pruned, and where there are any decayed parts, the Composition should be applied.

*Of the Mountain Service, or Mountain Ash (Sorbus Aucuparia, Linn.) Eng. Bot. t. 337.*

The Mountain Service is sometimes planted in orchards among fruit-trees; but I would recommend planting it in pleasure-grounds, plantations, or on lawns, for ornament, where the different varieties of the fruit have a beautiful effect in Autumn; and the fruit gathered, when full ripe, and laid by some time to soften, has a very agreeable acid taste.

The seeds, when properly dried, may be sown in Autumn in beds of light mould; taking care to keep them free from weeds in Summer. In the following Autumn they may be transplanted into beds, or quarters, (according to the number which you may wish to plant,) and trained either for dwarfs or standards.

By selecting the largest and finest fruit many varieties may be obtained from the seed; they may also be propagated from layers; but those who are fond of having a great variety, and keeping the sorts true, should graft them.

If trained up with straight clean stems, Service trees will grow to the height of thirty or forty feet; in that case they should be planted among forest trees, or in the back parts of large shrubberies. But those who wish to plant them as flowering shrubs, must head them down when young, to make them throw out horizontal shoots; they may then be planted among the

middling-sized shrubs, which will make a beautiful variety, both when in flower and when bearing fruit.

Mountain Service trees \* grow to a considerable size when properly managed, and are very much used by wheelers, &c. on account of the wood being all, what they call, heart-wood.

*Of the Maple-leaved Service, Wild Service, or Sorb. Pyrus Torminalis. Eng. Bot. 298.*

This tree grows wild at Paddington, and in other parts of England, and is frequently forty or fifty feet high, with a large spreading head, making a fine appearance, and deserves a place among forest-trees, and in extensive plantations and gardens. It bears large bunches of white flowers, succeeded by clusters of brown spotted fruit, which, when gathered full ripe, and laid by for some time, till it becomes soft, has a very agreeable tart flavour. This fruit is sometimes sold in the London markets in Autumn.

This tree may be raised from seed, which should be sown in Autumn, or by layers; but those who wish to raise them in the dwarf state should graft them very low, and train them from six to eight feet high. Some graft them on White thorns; but I prefer their own stocks. If these dwarfs are trained up with fine heads, they will have a very

\* The fruit of the Mountain Service is excellent food for game and other birds.

good effect in shrubberies. If intended for standards, train them up as high as you can : they will have a beautiful appearance in the back parts of shrubberies. They may also be trained without grafting, and planted on lawns for ornament. Some train them as Espaliers ; but this I do not approve of, as they are not so ornamental, neither do they bear so well.

The wood of this tree is also very useful for mechanical purposes.

## CHAPTER XVIII.

## OF THE ALMOND.

*Different Sorts of Almonds ; their Propagation, and the Method of Pruning them. — How to keep them during Winter.*

THE Almond belongs to the twelfth Class of Linnaeus, Icosandria Monogynia, being joined with the Peach, and was cultivated here in 1548. *Turner's Names of Herbes*, sign avij. ; it is named *Amygdalus communis*.

Almonds are beautiful trees for planting in shrubberies and plantations, and deserve a place in every pleasure-ground, on account of their coming so early into bloom, and for the use of their kernels.

*The following are the Sorts propagated in this Country for Ornament and Use, viz.*

1. TENDER-SHELLED ALMOND. *Duham. n. 2. t. 1. Pom. Franc. 1. p. 68. t. 5. Poit. et Turp. Fr. t. 75.*

2. SWEET ALMOND. *Duham. n. 5. t. 2. Pom. Franc. 1. p. 65. t. 1.*

3. COMMON, or BITTER ALMOND. *Pom. Franc. 1. p. 67. t. 3. Poit. et Turp. Fr. t. 144.*

4. SWEET JORDAN-ALMOND. *Pom. Franc.* 1. p. 67. t. 4.

5. HARD-SHELLED ALMOND. *Poit. et Turp. Fr.* t. 122.

6. DWARF ALMOND. *Duham. n. 8. t. 3. Poit. et Turp. Fr. t. 99.*

7. DOUBLE FLOWERING ALMOND. *Poit. et Turp. t. 99.*

The last two, being beautiful early flowering shrubs, are planted for ornament only.

Almonds are propagated by budding them upon Plum, Almond, or Peach stocks. The next Spring you may train them for standards, or let them grow for half-standards; but the common way is, to bud them as high as you wish the stem to be; and the second year after they may be planted out for good. If you are to transplant them into a dry soil, let it be done in October, when the leaves begin to decay; but if into wet ground, the month of February is the proper season. Almonds budded on Plum stocks thrive best in a wet soil, and on Almond and Peach stocks in a dry.

When the young trees are brought from the nursery, they should never be cut till the young shoots begin to break, — as directed for Peaches and Nectarines.

Almonds require nearly the same management in pruning as standard Apricots. After wet Autumns, when the wood is not well ripened, hard

Winters are apt to kill the shoots ; in that case, they should be cut down to the sound wood, taking care to cut out the cross shoots that rub against others, leaving the tree open in the middle, pruning the shoots about the same length as Apricots, and according to their strength. Never omit cutting out all the cankered parts and decayed wood.

Some plant these trees out as standards, and others as half-standards, according to the ground and situation ; always taking care to plant them in a sheltered place facing the South, intermixing them in the back of the shrubberies with the taller flowering shrubs ; or they may be planted on lawns for ornament, as they make a very beautiful appearance when in flower, or bearing fruit. If planted as dwarfs, they may be covered with poles stuck into the ground, thatching over the tops of the trees with some fern, or any other light covering, which will prevent the blossom from being killed by the frost in February and March. After the fruit is set, and the leaves so far out as to cover it, if fine weather, the covering may be removed in the latter end of April or beginning of May, which will ensure a plentiful crop of Almonds ; a very useful supply for the table in Autumn and Winter.

Those who have plenty of walling, sometimes plant Almond trees on walls, and sometimes on Espaliers.

Almonds may be preserved in dry sand, or bran, for use ; but they must be thoroughly dried on shelves, or boards, in any airy place before they are put into the sand or bran, otherwise they will get mouldy. They are preserved only for their kernels, the other part of the fruit being of no service,

## CHAPTER XIX.

## OF FILBERTS AND HAZEL-NUTS.

*The Sorts commonly cultivated in England. — Method of Culture. — How to keep them in Winter.*

FILBERTS and Hazel-nuts grow wild in woods and hedges, and are brought in great quantities to the London markets, and to those of other large towns throughout the kingdom; employing a great many poor families during the Autumn, who otherwise might have very little to do, and of course be a burden on the public.

This genus of plants is ranged in the eighth Order of Linnæus's twenty-first Class, Monœcia Polyandria, and named *Corylus Avellana*.

*The Sorts generally cultivated in England are the following, viz.*

1. THE LARGE COB-NUT. *Hooker Pom. Lond. t. 49.* Ripens in October.
2. THE LARGE LONG-NUT, which produces very fine large fruit.
3. THE BARCELONA, or SPANISH NUT, with large cups.
4. THE COMMON WOOD-NUT, with red-skinned kernels. *Langley Pom. t. 57. f. 2.*
5. THE FILBERT with white kernels. *Langley Pom. t. 57. f. 1.*

6. THE FILBERT with red kernels. *Poit. et Turp. Fr. t. 11.*

7. THE LARGE CLUSTER WOOD-NUT.

*Of Propagating and Pruning Nut-Trees.*

Filberts and Nuts of all kinds are propagated from seeds, layers, and suckers; but those who wish to have fine sorts should graft the trees, or lay down in March some of the straightest shoots, notched at a joint, pegging them into the ground; then cover them with earth about three inches thick, making basins round them with edges of mould about two inches higher than the surface of the ground to prevent the water's running off; water them sometimes in dry weather, and mulch them with some rotten leaves, to keep them moist. By the following Autumn they will be fit to take up and plant out in beds in the nursery, where they should remain about two years, planting them out in August where you wish them to remain for good. If any of the layers have not taken proper root, they may be left till the Autumn following.

Filberts and Nuts may be planted on the outsides of woods, or in the back parts of shrubberies and pleasure-grounds, or in large kitchen-gardens, in shady walks; or for the purpose of hiding sheds, cisterns, &c.

When they are raised from seed, it should be sown in Autumn, in a light earth; and it will be necessary to cover the beds all over with slates, flat

stones or bricks, to prevent the mice from eating the Nuts or carrying them off in Winter.

When at the Botanic Gardens, Chelsea, I once sowed several quarts of large Barcelona Nuts, in Pots, in two frames at a considerable distance from each other; the Nuts were all carried off by the mice in one night. On searching round the lining of a frame where we kept green-house plants in Winter, I found above a quart of the Nuts in one hoard, which I again sowed immediately, covering them over with slates; from these Nuts I raised some very fine plants.

The Barcelona Nut-tree is rather scarce in England, but it is well worth cultivating; it is a distinct species, and grows to a fine timber-tree. The Nuts that I sowed, as mentioned above, were produced from a fine tree in the Botanic Gardens at Chelsea. \*

Those who are not in possession of plants may procure them from Nuts fresh imported from Spain, by sowing them as before directed. Great quantities are imported annually under the name of Barcelona, or great Spanish Nuts.

When in the Nursery, Nut-trees should be trained with single straight stems, to form fine heads from three to six feet high; cut off the leading shoot at the height you would have the head formed, rubbing off all the lower buds,

\* This tree, at two feet and a half from the ground, measures about four feet in circumference.

and leaving only as many at top as you think will be sufficient to form a handsome head, and according to the strength of the stem.

Nuts, when intended for keeping, should be well-dried and packed in jars or boxes of dry sand, (and placed in a fruit-room, or dry cellar,) well covered down to preserve them from mice.

The shoots of Filbert and Nut-trees are very useful for staking green-house plants and raspberries, or for making withes to bind faggots, and for many other purposes in husbandry.

## CHAPTER XX.

## OF CHESNUTS.

*Different Sorts cultivated in England. — Chesnut Trees are excellent Timber. — How to Propagate, Plant, and Head them.*

THE Chesnut, *Castanea*, is a native of the South of Europe, and is said to take its name from Castanea, a city of Thessaly, where anciently it grew in great plenty. It belongs to the eighth order of Linnæus's twenty-first class, Monœcia Polyandria, and is named *Castanea Vesca*.

The sorts mostly cultivated in England are those commonly called Spanish Chesnuts, which run into great varieties when raised from seed; and a sort called, in America, Chinquapine, or Dwarf Virginian Chesnuts, *Castanea pumila*; but this is only raised for the sake of variety.

The former are very fine trees, and well worth cultivating both for use and ornament. The timber is reckoned equal to Oak, and, for making casks, even superior to it; as, when seasoned, it is not so liable to shrink or swell as Oak. These trees have also a very noble appearance, and are therefore very fit to plant in parks, &c.

Gerarde says, that in his time there were several

woods of Chesnuts in England, particularly one near Feversham, in Kent; and Fitz-Stephen, in a description of London, written by him in Henry the Second's time, speaks of a very noble forest which grew on the north part of it. This tree grows sometimes to an amazing size. Not to mention those abroad, there is one at Lord Ducie's, at Tortworth, in the county of Gloucester, which measures nineteen yards in circumference, and is mentioned by Sir Robert Atkyns, in his history of that county, as a famous tree in King John's time; and by Mr. Evelyn, in his *Sylva*, book 3d, chap. 7. p. 232., fourth edition, to have been so remarkable for its magnitude in the reign of King Stephen, as then to be called the Great Chesnut of Tortworth; from which it may reasonably be supposed to have been standing before the Conquest. Lord Ducie had a drawing of it taken and engraved in 1772. One of the prints is now in my possession, and was a present from my much esteemed friend, the late Captain William Locker, of the Royal Navy, and Lieutenant-Governor of Greenwich Hospital. \* Formerly a great part of London was

\* At Ashted-park, near Epsom, the seat of Richard Howard, Esq., there are a great many Spanish Chesnuts that were sown by a gardener now living, one of which, at three feet from the ground, measures seven feet in circumference, and has a trunk upwards of fifty feet high.

Since writing the above, I have seen the old gardener, Thomas Davie, (who is now 77 years old,) and have had some conversation with him. He says, that at the age of 15 he

built with Chesnut and Walnut tree; and at Sion House, the seat of the Duke of Northumberland, the stables are built with them from the old monastery at that place, which was taken down when the present mansion-house was built.

The best way of propagating Chesnut-trees is from seed, gathered when thoroughly ripe; which is generally about the latter end of October; but they should not be gathered till the husks begin to open, and the nuts appear of a brownish colour; they will then drop off themselves, and should be carefully picked up in the morning, and particularly after high winds; those which are intended for eating, or for seed, should be always suffered to drop of themselves; they will be found much better than those that are beaten down. If, however, the frost should set in early, you will be under the necessity of threshing them down, which should be done in a dry day. All that fall in the husk should be thrown in heaps in a shed, or other convenient place, and suffered to remain three weeks, or a month, in that state, to ripen. They should then be taken out of the husks, and the best picked out and laid up by themselves, after being

---

bought three shillings' worth of Chesnuts in London on purpose to treat his fellow-servants; but finding that they would not accept of them, he sowed them in a bed in a garden at Ashted, which then belonged to the Earl of Suffolk, and afterwards planted out the young trees where they now stand. These trees are, therefore, at this time sixty-two years old, from the seed.

well dried, on mats, or cloths, in a sunny situation. They should be laid up in the fruit-room or granary, on shelves, or on a dry floor. Remember to turn them frequently. The inferior ones will do for sowing, or they may be given to pigs or turkeys, who are very fond of them; they will be found very good for fattening poultry, especially turkeys. If during the Winter they should become damp or mouldy, they should be turned and carefully wiped; and if spread at a moderate distance from a fire, or dried in an oven after the bread is drawn, and then packed in boxes, or jars, with thorough dry sand, they will keep plump and good. Observe not to put them into the oven when too hot, as it will make them shrivel; and those for sowing must not be dried in this manner, as the heat of the oven would kill the germ. In a fine warm season, I have seen them ripen as well and grow nearly to as large a size as foreign ones, when the trees were healthy; but in a middling season they will do very well for sowing, or for fattening pigs and poultry. Be careful to preserve them from rats and mice, otherwise they will soon destroy vast quantities of them.

They may be sown in beds of light earth in the month of November, if it be a dry Autumn, drawing the drills about nine inches apart, and about three deep. Plant the nuts about an inch apart in the rows, with the points upwards, as bulbous roots are planted; then cover them with mould, and pat it down with the back of your rake. The beds

should be four or five feet wide, and a little raised towards the middle, to carry off the water. There should be alleys between the beds, about eighteen inches wide, and about two or three inches deep; these will receive and carry off the rain-water, which otherwise would be apt to rot the nuts. Thus, a five-foot bed will admit of six rows and a small edging next the alley. If you find the mice begin to attack them, the beds should be completely covered over with slates, flat stones, or bricks, till the nuts begin to spring; they must then be taken off. If it be a hard Winter, it will be necessary, before the stones or tiles are put on, to cover the beds with some rotten dung, rotten leaves, or old tan, to preserve the nuts from the frost. If it be a mild Winter, and the nuts have been sown in Autumn, they will begin to vegetate before Christmas; but if the Autumn be wet, I would advise not to sow them till some time in February, or the beginning of March. By the nuts being sown in rows, you will have room to hoe betwixt the rows, and be able to keep them clear of weeds, which you could not so easily do if they were sown broadcast. If it should prove a very dry Summer, it will be necessary to give them a good watering once or twice a week, till the plants begin to get strength. If they be well managed, by the end of October, or in the following Spring, you may transplant them into beds, in rows about a foot apart, and at the distance of four inches in the row, where they may remain for two years longer; taking care

to trim all the side-shoots, leaving only one straight stem. These beds may have alleys about the same width as before, with this difference, that the beds should be two inches lower than the alleys, which must be well trodden, to keep the earth from crumbling down into the beds. First level all your ground, then stretch the line from one end of the bed to the other, according to the size of the ground, and with your spade cut off the edging in the inside of the bed, throwing the mould towards the middle of it: then remove the line to the other side of the bed, which ought to be from four to six feet wide, and cut the other edge, throwing the mould into the bed as before. When this is done, throw up some of the mould on the top of the alley, to make it about two inches higher than the bed, and tread the alley well down. Then begin to plant your young trees in rows across the bed, a foot or fifteen inches apart, and about six inches in the row, digging the ground, and planting as you proceed, also beating up the edges of the alleys with the back of your spade, to keep the mould from tumbling down into the bed. Proceed thus till you have finished the bed, and so on till you have planted the whole. If it be dry weather, each bed should be watered as you finish planting it, which being made a little lower than the alleys will retain the water that you throw on it, and will prevent the rain from running off; if the dry weather continue long, mulch the beds as before directed. Observe to keep them free from weeds, watering

them as occasion requires, and trimming up the plants with only one stem. In this state they may remain two years; and if any of the plants require it, stake them to keep them straight. At the end of two years they will be fit for transplanting, and may be planted out for good, if they are properly fenced off from cattle; but if they are to be placed in an open exposure, they ought first to be planted out in a piece of ground, properly prepared for the purpose, at the distance of two feet from row to row, and one foot in the row. If they have been planted in the Autumn, (which I would always recommend, except in wet ground, or when the season is wet,) let them remain till next Spring twelve-month, and then head them down to two eyes above ground, cutting as near as may be to an eye, and sloping to the North, that the shoot which is thrown out may cover the stem in the first season; which, if the business be rightly performed, it will do, and grow to the length of six or seven feet, according to the vigour of the stem. If they are not headed-down in this manner, you will never have straight handsome trees. If the ground be properly fenced off from cattle, those that are planted out for good, at three years old, must be treated in the same manner after the first or second year. It may, however, be necessary to observe, that young trees must not be headed-down immediately after transplanting: they ought to be well rooted before that operation is performed; and it is also worthy of remark, that the

larger the stems are when they are headed, the stronger and more luxuriant will the shoots be.

Chesnut trees are frequently grafted, to make them bear fruit early; but these are unfit for timber. In France, the wild or ungrafted Chesnut is called *Châtaignier*; and the grafted or cultivated sort, *Maronnier*.

I did not, at first, intend to have said any thing of Chesnuts and Walnuts; but, as most people are fond of them, and as they are generally served up at table with the dessert, it seemed proper to give some account of their culture, &c.

## CHAPTER XXI.

## OF WALNUTS.

*Different Sorts described. — Their Propagation, Planting, and Trimming. — Great Utility of the Timber. — Method of Keeping Walnuts in the Winter.*

THE Common Walnut tree is a native of Persia; and the time of its introduction here is not known with certainty. It is mentioned in *Turner's Herb.* 1562. part 2. fol. 23. verso. It belongs to the eighth Order of the twenty-first Class of Linnæus's System, Monœcia Polyandria; and named *Juglans Regia*.

Those commonly cultivated in this country are the following varieties of the common Walnut:

1. The Double-bearing Walnut.
2. The English Walnut. *Langley Pom. t. 58. f. 9, 10. Poit. et Turp. Fr. t. 34.*
3. The large French Walnut. *Langley Pom. t. 58. f. 3. 5. Poit. et Turp. Fr. t. 140.*
4. The Thin-shelled Walnut.
5. The Late-ripe Walnut.

The Hickery Nut from North America, *Juglans alba*; the fruit of which is small but well flavoured, is also raised here, as is the Black Virginia Walnut, *Juglans nigra*; but this latter is cultivated chiefly

for its timber. There are several other sorts from North America, which are planted for variety.

The best way of raising these trees is from the nut, which should be gathered when full ripe; those with thin shells are to be preferred for this purpose. Walnuts, unless a sharp frost sets in, which is very seldom the case before they are ripe, should be suffered to remain on the trees till they begin to drop of themselves: shaking of the tree will then bring them down. Beating them down with poles, as is usually done, injures the tree very much by breaking the young shoots; beside, the nuts never keep well when they are threshed down too early.

The nuts may be sown in drills in the same manner as Chesnuts: the best time for doing this, if the season be dry, is Autumn; and the nuts must be thoroughly dry, otherwise they will be apt to rot before they vegetate. If the Autumn be wet, they may be sown in the month of February or the beginning of March, and ought to be covered over as directed for Chesnuts, to preserve them from mice. If they thrive well, they will be fit for transplanting the first Autumn after sowing; but if not, they should be suffered to remain another year. Bed them out in the same manner as directed for Chesnuts, transplanting every second or third year, until they are planted out for good. This will cause them to throw out fine horizontal roots, and bring them into a bearing state much sooner

than when they make deep tap-roots. The common time a Walnut tree takes to bear from the nut, is above twenty years. Train them up with fine single stems to about seven feet high, before you suffer them to form heads; the branches will then be out of the reach of cattle. The time of transplanting them out depends on the progress that they have made in the nursery; they should be suffered to continue there until they have grown to a tolerable size, and to the height just mentioned as proper for standards. The ground, where they are to be planted, should be well ploughed or trenched, and the trees planted, at first, in rows six feet apart, and the same distance from tree to tree in the rows, in the quincunx order, and thus to remain till they come into bearing. This will be necessary, as there is no dependance on the sort of fruit that trees raised from seed may produce. After you have made choice of those which bear the best fruit, the others may be planted out for timber, or cut down for stakes, or any other purpose. The trees left for bearing must be thinned, by taking out every other tree in the remaining rows, as they increase in size, till they stand at the distance proper for full-grown trees; which may be from twenty-four to forty-eight feet, according to the richness of the soil and the progress which the trees make.

In trimming the stems of Walnut-trees, cut off the shoots and small branches close to the bole :

and in lopping, cutting out cross branches, or such as are damaged by winds and other incidents, always cut at a fork or eye, otherwise part of the branch will die and injure the tree. But, whether only a part or the whole of a branch be cut off, the composition ought immediately to be applied.

Formerly Walnut-tree was much used for building, and for household furniture; but mahogany and other foreign timbers have now in a great measure superseded it, especially in the latter article. This timber will do very well for uprights, but is rather too brittle for joists, rafters, &c., and when properly polished, it looks very well in chairs, tables, bureaux, &c. It is at present a good deal used for gunstocks. Walnuts thrive best in a deep rich soil, but will do very well in a chalky soil, as may be seen on the hills in Surrey, in the neighbourhood of Leatherhead, Godstone, and Carshalton; and at Beddington-Park, the seat of the ancient family of the Carews, there are many fine old Walnut-trees. These trees are well worth cultivating; as the yearly value of the fruit that they bear is very considerable.\* There is a great deal of money made,

\* At Beddington, about 50 Walnut-trees (and not above half of that number full bearers) have been let at 30*l.*, 40*l.*, and 50*l.*, according to the crop; and it is supposed, that in a good season the renter clears 50*l.* by the bargain.

Beddington was noted in Queen Elizabeth's time for the finest Orangery in England.

in plentiful years, by thinning of the nuts for pickling, both for home consumption and also for exportation. The leaves of Walnuts steeped in boiling water, and that infusion mixed with lime-water, soap-suds, and urine, is found very efficacious for destroying slugs and worms in the ground, and insects on trees.

Walnuts for keeping should be suffered to drop of themselves, and afterwards laid in an open airy place till they are thoroughly dried; then pack them in jars, boxes, or casks, with fine clean sand, that has been well dried in the sun, in an oven, or before the fire, in layers of sand and Walnuts alternately; set them in a dry place, but not where it is too hot. In this manner I have kept them good till the latter end of April. Before you send them to table, wipe the sand clean off; and, if you find that they have become shrivelled, steep them in milk and water for six or eight hours before they are used; this will make them plump and fine, and cause them to peel easily.

Walnut trees have been propagated by grafting and budding. They are frequently injured by Spring frosts: to avoid this, it is a practice in Switzerland to graft the common stocks with the late-ripe variety, which does not produce its fruit before the month of May or June.

## CHAPTER XXII.

## OF GRAFTING AND BUDDING.

*Four different Ways of Grafting, with Observations. — On using the Composition, instead of Grafting-clay. — Of Budding, with Observations, &c.*

**G**RAFTING is the taking of a shoot from one tree, and inserting it into another, in such a manner as that both may unite closely and become one tree; this is called, by the ancient writers on husbandry and gardening, *incision*, to distinguish it from inoculating, or budding, which they call *inserere oculos*.

I have taken a great deal of pains to trace the practice of grafting to its origin; but without success, as no author that I have perused gives any satisfactory account of it; it is, however, allowed by all to be very ancient.

The use of grafting is to propagate any curious sorts of fruits so as to be certain of the kinds; which cannot be done by any other method; for, as all the good fruits have been accidentally obtained from seeds, so of the seeds of these, when sown, many will degenerate, and produce such fruit as is not worth the cultivating; but when shoots are taken from such trees as produce good fruit, these will never alter from their kind,

whatever be the stock or tree on which they are grafted.

The principle or philosophy of grafting is somewhat obscure ; and had not accident given the first hint, all our knowledge of Nature would never have led us to it. The effect is ordinarily attributed to the diversity of the pores or ducts of the graft from those of the stock, which change the figure of the particles of the juices in passing through them to the rest of the tree.

Mr. Bradley, on occasion of some observations by Agricola, suggests something new on this head. The stock grafted on, he thinks, is only to be considered as a fund of vegetable matter which is to be filtered through the cion ; and digested, and brought to maturity, as the time of growth in the vessels of the cion directs. A cion, therefore, of one kind, grafted on a tree of another, may be rather said to take root in the tree that it is grafted in, than to unite itself with it ; for it is visible, that the cion preserves its natural purity and intent, though it be fed and nourished by a mere crab ; which is, without doubt, occasioned by the difference of the vessels in the cion from those of the stock ; so that grafting may be justly compared to planting.

In prosecution of this view of that ingenious author, we add, that the natural juices of the earth, by the secretion and comminution in passing through the roots, &c., before they arrive at the cion, must doubtless arrive there half elabor-

ated and concocted, and so disposed for a more easy, plentiful, and perfect assimilation and nutrition; whence the cion must necessarily grow and thrive better and faster than if it were put immediately in the ground, there to live on coarser diet and harder of digestion; and the fruit produced by this further preparation in the cion must be finer, and further exalted, than if fed immediately from the more imperfectly prepared and altered juices of the stock. It may, perhaps, be thought unnecessary to say any thing here on grafting, as it has been so fully treated of by Mr. Miller, and other writers on gardening; but, as this treatise is principally on pruning and training, grafting seems naturally connected with it.

I persuade myself, therefore, that a few instructions in grafting will not be unacceptable, as they may save the reader the trouble of turning to other books; especially as they are more particularly intended for the grafting of old trees, and such as are found, when they come to bear, to be a different sort from what was expected: for although nurserymen in general are very careful in these matters, yet through the inattention of their men, or some mistake, or by an improper choice of the sorts, it will frequently happen, that after waiting thirteen or fourteen years, when the trees come to bear, the fruit is found of a bad quality, and not fit for use; so that new grafting or budding is absolutely necessary.

I shall, therefore, give what directions may be

necessary on that subject, to render it plain and easy to those who have not been regularly instructed in the art of grafting from general practice ; and add a method which I have followed for some years, and which I flatter myself will be found an improvement.

The shoots used in grafting are called cions, or grafts : and in the choice of these the following directions should be carefully observed. 1st. That they are shoots of the former year ; for when they are older they never succeed well. 2dly. Always to take them from healthy fruitful trees ; for, if the trees from which they are taken be sickly, the grafts very often partake so much of the distemper as rarely to get the better of it, at least for some years ; and when they are taken from young luxuriant trees, whose vessels are generally large, they will continue to produce luxuriant shoots, but are seldom so productive as those which are taken from fruitful trees whose shoots are more compact, and the joints closer together ; at least it will be a great number of years before the luxuriant grafts begin to produce fruit, even if managed with the greatest skill. 3dly. You should prefer those grafts which are taken from the lateral or horizontal branches, to those from the strong perpendicular shoots, for the reasons before given.

These grafts, or cions, should be cut off from the trees before the buds begin to swell, which is generally three weeks or a month before the season for grafting ; therefore, when they are cut off, they should be laid in the ground with the cut

downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying; if a small joint of the former year's wood be cut off with the cion, it will preserve it the better, and when they are grafted this may be cut off; for at the same time the cions must be cut to a proper length before they are inserted in the stocks; but, till then, the shoots should remain of their full length, as they were taken from the tree, which will better preserve them from shrinking; if the cions are to be carried to a considerable distance, it will be proper to put their ends into a lump of clay, and to wrap them up in moss, which will preserve them fresh for a month, or longer; but these should be cut off from the trees earlier than those which are to be grafted near the place where the trees are growing.

Having given directions for the cions and grafts, we next come to that of the stock, which is a term applied to the trees intended for grafting; these are, either such old trees as are already growing in the places where they are to remain, whose fruit is intended to be changed; or young trees, which have been raised in the nursery for a supply to the garden; in the former case, there is no other choice, than that of the branches, which should be such as are young, healthy, well situated, and have a smooth bark. If these trees are growing against walls, or espaliers, it will be proper to graft six, eight, or ten branches, according to the size of the trees, by which they will be much sooner furnished.

with branches again, than when a less number of cions are put in : but in standard trees, four, or at most six, cions will be sufficient.

In the choice of young stocks for grafting, you should always prefer such as have been raised from the seed, and that have been once or twice transplanted.

Next to these, are those stocks which have been raised from cuttings, or layers ; but those which are suckers from the roots of other trees should always be rejected ; for these are never so well rooted as the others, and constantly put out a great number of suckers from their roots, whereby the borders and walks of the garden will be always pestered during the Summer season ; these are not only unsightly, but they also take off part of the nourishment from the trees.

If these stocks have been allowed a proper distance in the nursery where they have grown, the wood will be better ripened and more compact, than those which have grown close, and have been there drawn up to a greater height : the wood of these will be soft, and their vessels large ; so that the cions grafted into them will shoot very strong ; but they will be less disposed to produce fruit than the other ; and when trees acquire an ill habit at first, it will be very difficult to reclaim them afterward.

Having directed the choice of cions and stocks, we come next to the operation ; in order to which we must be provided with the following tools :

1. A neat small hand-saw, for cutting off the heads of large stocks.

2. A good strong knife, with a thick back, to make clefts in the stocks.

3. A sharp pen-knife, or budding-knife, to cut the grafts.

4. A grafting-chisel and a small mallet.

5. Bass strings, or woollen yarn, to tie the grafts with; and such other instruments and materials as you should find necessary, according to the sort of grafting which you are to perform.

6. A quantity of clay, which should be prepared a month before it is used, and kept turned and mixed, like mortar, every other day: this is to be made in the following manner.

Get a quantity of strong fat loam (in proportion to the quantity of trees intended to be grafted); then take some new stone-horse dung, and break it in among the loam; and if you cut a little straw or hay, very small, and mix amongst it, the loam will hold together the better; and if there be a quantity of salt added, it will prevent the clay from dividing in dry weather: these must be well stirred together, putting water to them after the manner of making mortar; it should be hollowed like a dish, filled with water, and kept every other day stirred; but it ought to be remembered, that it should not be exposed to the frost, or drying winds; and the oftener it is stirred and wrought the better.

Of late years, some persons have made use of

another Composition for grafting, which they have found to answer the intention of keeping out the air better than the clay before described. This is composed of turpentine, bees-wax, and rosin, melted together; which, when of a proper consistence, may be put on the stock round the graft, in the same manner as the clay is usually applied; and, though it be not above a quarter of an inch thick, it will keep out the air more effectually than the clay; and, as cold will harden this, there is no danger of its being hurt by frost, which is very apt to cause the clay to cleave, and sometimes to fall off; and when the heat of the Summer comes on, this mixture will melt, and fall off without any trouble. In the using of this, there should be a tin or copper pot, with conveniency under it to keep a very gentle fire with small coal; otherwise the cold will soon condense the mixture; but you must be careful not to apply it too hot, lest you injure the graft. A person who is a little accustomed to this Composition will apply it very fast; and it is much easier for him to work with than clay, especially if the season should prove cold.

There are several ways of grafting, but five principal ones; [See PLATE XI.]

1. Grafting in the rind, called also shoulder-grafting; which is only proper for large trees: this is called crown-grafting, because the grafts are set in form of a circle, or crown; and it is generally performed about the latter end of March, or the beginning of April.

2. Cleft-grafting, which is also called stock, or slit-grafting; this is proper for trees or stocks of a lesser size, from an inch to two inches, or more, diameter: this grafting is to be performed in the months of February and March, and supplies the failure of the escutcheon way, which is practised in June, July, and August.

3. Whip-grafting, which is also called tongue-grafting: this is proper for small stocks of an inch, half an inch, or less diameter; it is the most effectual way of any, and is most in use.

4. Grafting by approach, or ablactation: this is practised when the stock that you would graft on, and the tree from which you take your graft, stand so near together, that they may be joined; and should be performed in the month of April. This method, which is also called inarching, is chiefly used for Jasmines, Oranges, and other tender exotic trees.

5. Grafting in the root: This is of later invention than any of the former ways, and in many circumstances may be an improvement on them all.

We come next to the manner of performing the several methods of grafting.

The first, which is termed rind, or shoulder-grafting, is seldom practised but on large trees, where either the head or the large branches are cut off horizontally, and two or four cions put in, according to the size of the branch, or stem: in doing this, the cions are cut flat on one side, with a shoulder to rest upon the crown of the stock; then

the rind of the stock must be raised up, to admit the cion between the wood and the bark of the stock, which must be inserted about two inches, so as that the shoulder of the cion may meet, and closely join the crown of the stock; and after the number of cions is inserted, the whole crown of the stock should be well clayed over, leaving two eyes of the cions uncovered therewith, which will be sufficient for shooting. This method of grafting was much more in practice formerly than it is at present; and the discontinuance of it was caused by the ill success with which it was attended; for, as these cions were placed between the rind of the stock and the wood, they were frequently blown out by strong winds, after they had made large shoots, which has sometimes happened after five or six years growth; so that whenever this method is practised, there should be some stakes fastened to support the cions until they have almost covered the stock.

- The next method is termed cleft, or stock-grafting: this is practised upon stocks, or trees, of a smaller size, and may be used with success where the rind of the stock is not too thick, whereby the inner bark of the cion will be prevented from joining to that of the stock. This may be performed on stocks, or branches, that are more than one inch diameter: the head of the stock, or branch, must be cut off with a slope, and a slit made the contrary way, in the top of the slope, deep enough to receive the cion, which should be cut sloping like a wedge, so as to fit the slit made in the

stock ; being careful to leave that side of the wedge which is to be placed outward, much thicker than the other ; and in putting the cion into the slit of the stock, there must be great care taken to join the rind of the cion to that of the stock ; for if these do not unite, the grafts will not succeed : when this method of grafting is used to stocks that are not strong, it will be proper to make a ligature of bass, to prevent the slit of the stock from opening ; then the whole should be clayed over, to prevent the air from penetrating the slit, so as to destroy the grafts, only leaving two eyes of the cions above the clay for shooting.

The third method is termed whip, or tongue-grafting, which is the most commonly practised of any by the nursery-men near London, especially for small stocks, because the cions much sooner cover the stocks in this method than in any other.

This is performed by cutting off the head of the stocks sloping : then there must be a notch made in the slope, toward the upper part, downward, a little more than half an inch deep, to receive the cion, which must be cut with a slope upward, and a slit made in this slope like a tongue, which tongue must be inserted into the slit made in the slope of the stock, and the cion must be placed on one side of the stock, so as that the two rinds of both cion and stock may be equal, and join together exactly ; then there should be a ligature of bass to fasten the cion, so as that it may not be easily displaced, and afterwards clay it over as in the former methods.

The fourth method of grafting is termed inarch-

ing, grafting by approach, or ablactation. This is only to be performed when the stocks that are designed to be grafted, and the tree from which the graft is to be taken, stand so near together, as that their branches may be united. It is commonly practised on tender exotic plants, and some other sorts which do not succeed in any of the other methods.

In performing this operation, a part of the stock, or branch, must be slit off about two inches in length, observing always to make choice of a smooth part of the stock; then a small notch should be made in this slit of the stock downward, in the same manner as hath been directed for whip-grafting; the branch of the tree designed to be inarched should have a part slit off in like manner as the stock, and a slit made upward in this, so as to leave a tongue, which tongue should be inserted into the slit of the stock; observing to join their rinds equally, that they may unite well together; then make a ligature of bass, to keep them exactly in their situation, and afterwards clay this part of the stock over well, to keep out the air: in this method of grafting, the cion is not separated from the tree until it is firmly united with the stock, nor is the head of the stock, or branch, which is grafted, cut off till this time, and only half the wood pared off with a slope, about three inches in length, and the same of the cion, or graft.

This method of grafting is not performed so early in the season as the others; it being done in the month of April, when the sap is flowing, at which

time the cion and stock will join together, and unite much sooner than at any season.

The Walnut, Fig, and Mulberry, will take by this method of grafting, but neither of these will succeed in any of the other methods; there are also several sorts of evergreens that may be propagated by this method of grafting; but all the trees that are grafted in this way are weaker, and never grow to the size of those which are grafted in the other method; therefore this is rarely practised, but on such sorts of trees as will not take by the other methods.

The fifth method is performed by cutting the clean smooth roots of the stocks in pieces five or six inches long, and as large, or a little larger, than the graft of the same species you are to put in it. Let them be whip-grafted, and tied together very close, so as to prevent the wet from affecting the wounded parts, and plant them so deep, that the graft, which should be four or five inches long, may be about half buried under the surface. By this method the grafts themselves will root, and a nearer similitude preserved to the tree whence the grafts are taken; nay, after two or three years, the stock may be cut quite away, and the graft left to maintain itself. In practising this method, the grafts may be an inch or two longer than is directed for the others. This is an expeditious way of obtaining a new plant, but such grafts differ but little from cuttings or layers, and do not possess the advantages derivable from a vigorous seedling stock.

*Observations on Grafting.*

In a long continuance of dry weather the grafts very frequently fail of taking ; sometimes, no doubt, owing to the improper choice of the grafts, as well as to the dry weather. Great care should always be taken not to graft with weak shoots, particularly those taken from near the top. Always take your grafts from the lower end of the shoots, and observe that the wood is plump and fresh ; for such as are shrivelled seldom or never take. Where any have missed in the Spring, I would advise to cut off, about the middle or latter end of June, some fine healthy grafts of the sort that you wish to graft with ; open the bark in the same manner as you do for budding (of which hereafter), and insert the graft with a piece of the former year's wood on it ; after you have done this, rub in, with a brush, some of the Composition in a liquid state ; then wrap your bass round it, as is done for Spring grafting, leaving about three eyes on the shoot, which should be tied on with the bass as tight as you can ; then cover the outside of the bass, thus tied up, with the Composition, to the thickness of about one-eighth of an inch, observing also to cover the end of the shoot with the same, to exclude the air and wet. In about three weeks, or a month, look over the grafts to see if they have taken. When the graft begins to swell, it will throw off the Composition : when that is the case, always remember to apply more, to prevent the air from penetrating the incision.

In the month of September, you should examine whether the wounds are all healed up, and the two barks perfectly united; if they are, you may slacken the bass; and if they are perfectly healed up, it may be taken off: but if not, the bass must again be tied on, and covered with the Composition as before directed; letting it remain till the following Spring. You may then take the bass off, and, if you find that the two barks have separated during the Winter, with the point of a sharp knife cut out all the brown part of the bark (which, if left, would infallibly bring on the canker), and rub the Composition into the wound. If your grafts have produced strong leading shoots, the tops of them should be pinched off with the finger and thumb; but if they have not shot strong, they should not be cut till the Spring, when they should be cut to three or four eyes, according to their strength, to make them produce horizontal shoots, and for handsome heads. This grafting should always be performed in moist or cloudy weather.

I have already, in the Chapter on APPLE-TREES, mentioned the advantages to be derived from using the Composition instead of grafting-clay, and also given some directions for the same. Rubbing a little of it into the incision will effectually prevent the canker, and in applying it round the graft, a much less quantity will be sufficient than of the clay; as it need not be more than three inches round in grafting small stems or shoots, and so in proportion for those which are larger. The Com-

position will keep the cion moist, and will not crack and fall off in dry weather as clay does. The Composition to be used in grafting should be of such a consistence as to work easily with the hand, or a knife, or small trowel, rather softer than grafting-clay generally is. Any person who gives this method a fair trial, will find it to be a sure, neat, and expeditious way of grafting.

Grafting, or budding, should be performed as near to the upper side of a bud as possible. The most proper place for inserting the cion, or bud, is at the joint a little above the cross shoot.

The season for grafting must be regulated by the weather. Our climate is so uncertain in the Spring, that it is better to defer it, till the circulation of the sap is brisk, and the buds of the stocks are beginning to break into leaves: observing only that the weak shoots of tender trees will not admit of being so long cut as the more hardy. It is indispensably necessary never to graft while it actually freezes, or rains.

*Inoculation, or Budding.*

This is commonly practised upon all sorts of stone-fruit in particular; such as Peaches, Nectarines, Cherries, Plums, &c.; as also Oranges and Jasmines; and is preferable to any sort of grafting for most kinds of fruit. The method of performing it is as follows: you must be provided with a sharp pen-knife, or what is commonly called a budding-knife, having a flat haft, (the use of which

is to raise the bark of the stock to admit the bud,) and some sound bass mat, which should be soaked in water to increase its strength, and make it more pliable : then, having taken off cuttings from the trees that you would propagate, you should choose a smooth part of the stock, above five or six inches above the surface of the ground, if designed for dwarfs, and for half-standards at three feet ; but for standards they should be budded six or more feet above the ground ; then with your knife make an horizontal cut across the rind of the stock, and from the middle of that cut make a slit downwards about two inches in length, so that it may be in the form of a T ; but you must be careful not to cut too deep, lest you wound the stock : then, having cut off the leaf from the bud, leaving the foot-stalk remaining, you should make a cross cut about half an inch below the eye, and with your knife slit off the bud with part of the wood to it, in form of an escutcheon : this done, you must with your knife pull off that part of the wood which was taken with the bud, observing whether the eye of the bud be left to it or not (for all those buds which lose their eyes in stripping should be thrown away, being good for nothing); then having gently raised the bark of the stock where the cross incision was made, with the flat haft or handle of your knife clear of the wood, you should thrust the bud therein, observing to place it smooth between the rind and the wood of the stock, cutting off any part of the rind belonging to the bud which may

be too long for the slit made in the stock ; and, having thus exactly fitted the bud to the stock, you must tie them closely round with bass mat, beginning at the under part of the slit, and so proceed to the top ; taking care that you do not bind round the eye of the bud, which should be left open.

When your buds have been inoculated three weeks or a month, you will see which of them have taken ; those which appear shrivelled and black are dead ; but those which remain fresh and plump, you may be sure are joined ; and at this time you should loosen the bandage, which, if not done in time, will pinch the stock, and greatly injure, if not destroy, the bud.

In the March following you must cut off the stock about three inches above the bud ; sloping it, that the wet may pass off, and not enter the stock : to this part of the stock left above the bud, it is very proper to fasten the shoot which proceeds from the bud, and which would be in danger of being blown out, if not prevented ; but this must continue no longer than one year, after which it must be cut off close above the bud, that the stock may be covered thereby.

The time for inoculating is, from the middle of June until the middle of August, according to the forwardness of the season, and the particular sorts of trees to be propagated ; but the time may be easily known, by trying the buds, whether they will come off well from the wood or not. However, the most general rule is, when you observe

the buds formed at the extremity of the same year's shoots, which is a sign of their having finished their Spring growth.

The first sort commonly inoculated is the Apricot, and the last the Orange-tree, which should never be done until the middle of August; and in doing of this work, you should always make choice of cloudy weather; for if it be done in the middle of the day, in very hot weather, the shoots will perspire so fast as to leave the buds destitute of moisture: nor should you take off the cuttings from the tree long before they are used; but if you are obliged to fetch your cuttings from some distance, as it often happens, cut off the leaves, but let all the footstalks remain; then wrap the cuttings up in wet moss, and put them in a tin box (carrying them in a tin case with water being now disused) to exclude the air; in this manner you may carry them to any reasonable distance in good condition for inoculating.

It is a very improper practice of many persons, to throw their cuttings into water; for this so saturates the buds with moisture, that they have no attractive force left to imbibe the sap of the stock; for want of which they very often miscarry.

But before I quit this subject, I beg leave to observe, that, though it is the ordinary practice to divest the bud of that part of the wood which was taken from the shoot with it; yet, in many sorts of tender trees, it is best to preserve a little wood to the bud, without which they often fail.

The not observing this has occasioned some people to imagine, that certain sorts of trees are not to be propagated by inoculation; whereas, if they had performed it in this method, they might have succeeded, as I have several times experienced.

The next thing necessary to be known by those who would practise this art is, what trees will take and thrive, by being grafted, or inoculated, upon each other; and here there have been no sure directions given by any of the writers on this subject; for there will be found great mistakes in all their books, in relation to the matter; but, as it would extend this article too far, if all the sorts of trees were to be here enumerated which will take upon each other by grafting or budding, I shall only give such general directions as, if attended to, will be sufficient so to instruct persons, as that they may succeed.

All such trees as are of the same genus, *i. e.* which agree in their flower and fruit, will take upon each other: for instance, all the Nut-bearing trees may be safely grafted on each other, as may also all the plum-bearing trees, under which head I reckon not only the several sorts of Plums, but also the Almond, Peach, Nectarine, Apricot, &c. which agree exactly in their general characters, by which they are distinguished from all other trees; but, as many of these are very subject to emit large quantities of gum from the parts of the trees which are deeply cut and wounded; in the tender trees of this kind, viz. Peaches, and Nectarines, which are

most subject to this, it is found to be the surest method to bud or inoculate these sorts of fruits.

All such trees as bear cones will do well upon each other, though they may differ in one being ever-green, and the other shedding its leaves in Winter; as observable in the Cedar of Libanus, and the Larch-tree, which are found to succeed upon each other very well; but these must be grafted by approach; for they abound with a great quantity of resin, which is apt to evaporate from the graft if separated from the tree before it is joined with the stock, whereby they are often destroyed; as also the Laurel on the Cherry, or the Cherry on the Laurel. All the mast-bearing trees will also take upon each other, and those which have a tender soft wood will do well if grafted in the common way; but those that are of a more firm contexture, and are slow growers, should be grafted by approach.

By strictly observing this rule, we shall seldom miscarry, provided the operation be rightly performed, and at a proper season, unless the weather should prove very bad, as it sometimes happens, whereby whole quarters of fruit-trees miscarry, and it is by this method that many kinds of exotic trees are not only propagated, but also rendered hardy enough to endure the cold of our climate in the open air; for, being grafted upon stocks of the same sort which are hardy, the grafts are rendered more capable of enduring the cold, as hath been experienced by most of our valuable fruits now in

England, which were formerly transplanted hither from more southerly climates, and were at first too impatient of our cold to succeed well abroad; but have been, by budding or grafting upon more hardy trees, rendered capable of resisting our severest cold.

These different graftings seem to have been greatly in use among the Ancients, though they were certainly mistaken in the several sorts of fruits which they mention as having succeeded upon each other; as the Fig upon the Mulberry, the Plum upon the Chesnut, with many others of the like kind; most of which have been tried by Mr. Miller, and found not to succeed; therefore, what has been advanced on this head by the Ancients is not founded on experience: or, at least, they did not mean the same plants which at present are called by those names; though I cannot help thinking that we are apt to pay too much deference to the writings of the Ancients, in supposing them seldom to be mistaken, or to assert a falsehood; whereas, if their works are carefully examined, it will be found that they have often copied from each other's writings without making experiments to prove the truth of their assertions; and it is well known, that the ranging of plants before Cæsalpinus's time (which is about 200 years since) was, by their outward appearance, or from the supposed virtues of them, a method that is now justly exploded; and it has been observed, from many repeated trials, that, how-

ever plants may resemble each other in the shape and make of their leaves, manner of shooting, &c. unless they agree in their fruit, and their other distinctive characters, they will not grow upon each other, though performed with ever so much art.

*Observations on Budding Pear-trees on Walls.*

When the Pear-trees which are grafted in the Spring have not taken, I would advise to cut them off, a little below the graft, at a joint or bud. The tree will then throw out a great number of healthy shoots: rub these all off, except so many as will be sufficient to fill the wall; nailing those up, to prevent the wind from breaking them.

About the latter end of July the shoots will be fit to bud, which should be done about that time. I would recommend leaving a little of the wood on the inside of the bud when inserted into the stock, rubbing in the Composition, and tying on the bass as before.

Last Spring I grafted some Summer Bonchrêtiens with the Bergamot de Pâque (or Easter Bergamot), and Pear d'Auch, most of which failed. I then cut them off below the grafts, and in July following they had produced shoots from five to six feet long, which I budded in the latter end of that month with the before-mentioned sorts, which all took. About the beginning of September I ordered a man to slacken the basses; which having left too loose, the barks began to

separate. I then made him tighten them, letting them remain till the following Spring. About the beginning of April, when I saw the buds begin to shoot, I cut the shoots near to the buds, but finding many where the bark had not united, and some of the eyes apparently dead, I took a sharp pen-knife and cut out all the decayed bark, rubbing in the Composition, in the liquid state, till the hollow parts were filled up ; I then smoothed it off, with the finger, even with the bark of the stock. I also rubbed some of the Composition over those eyes that were in the worst state, being quite black ; but with very little hope of recovery. To my great astonishment, many of those which seemed perfectly dead, recovered, and, by the middle of July, had shoots from five to six feet long (many of the shoots which took well have fruit-buds formed for next year), and covered a space of wall larger than a young tree would have done in eight years ; all the cavities where I cut out the dead bark, and applied the Composition, were, in the course of the Summer, filled up with sound wood, and the bark between the stocks and grafts perfectly united.

Three years ago I budded some Brown Beurrés and Crasannes with Pear d'Auch, one of which now covers a wall sixteen feet high and fifteen feet long, and has more fruit on it this year than a maiden tree would have produced twenty years after planting.

I never recommend budding or grafting of old

trees, except when you have bad sorts, or more of any sort than you want for a supply : in that case, I would recommend to bud or graft with Pear d'Auch, Colmars, and Winter Bonchrêtiens, which keep much longer than Beurrés, Crasannes, &c.

It will be necessary to give some directions for standards that have been grafted in the Spring, and have missed. In such case, they should be cut below the graft, as directed for wall-trees ; and when so treated, they will throw out a great number of shoots, which should by no means be too soon thinned, as in that case they will be liable to be broken by the wind. You may begin to take off the weakest shoots about the latter end of May, or beginning of June. About the middle of the latter month, they will have acquired considerable strength ; you will then thin them ; leaving as many strong regular shoots, and of those nearest the top of the stem as will form a handsome head. If the stem be very strong it will be necessary, perhaps, to leave more than you intend to bud, on purpose to receive the sap, which will flow in great abundance from a large trunk, and, without this precaution, would be apt to burst the shoots, if there be not a sufficient number to receive it. I have often seen shoots as large as my arm, burst by a superabundance of sap. When that is likely to happen, the best thing you can do is to scarify the shoots, and rub a little of the Composition into the wound.

## CHAPTER XXIII.

## OF A GARDEN.

*Its Situation, Size, Soil, and Form.—Of Watering,  
Draining, &c.*

*Of the Melon-ground.*

A GARDEN, if possible, should be on a gentle declivity towards the South, a little inclining to the East, to receive the benefit of the morning sun. If it be situated in a bottom, the wind will have the less effect upon it; but then damps and fogs will be very prejudicial to the fruit and other crops; and if situated too high, although it will in a great measure be free from damps and fogs, it will be exposed to the fury of the winds, to the great hurt of the trees, by breaking their branches, and blowing down the blossoms and fruit. A garden should be well sheltered from the North and East, to prevent the blighting winds from affecting the trees; and also from the Westerly winds, which are very hurtful to gardens in the Spring or Summer months. If a garden be not naturally sheltered with gentle rising hills, which are the best shelter of any, plantations of forest trees, made at proper dis-

tances, so as not to shade it, will be found the best substitute. At the same time there ought to be a free admittance for the sun and air. On that account, a place surrounded by woods is a very improper situation for a garden, or orchard, as a foul stagnant air is very unfavourable to vegetation; and it is also observed, that blights are much more frequent in such situations than in those that are more open and exposed.

I have recommended the practice of intermixing fruit trees in shrubberies and plantations of this kind, to several gentlemen, who have adopted it with success. While the fruit trees are in flower, they are a great ornament to the shrubberies; and in Summer and Autumn the different colours of the fruit have a beautiful appearance. Add to this the advantage of a plentiful supply of fruit for the table, and for making cider and perry; and if some cherries are interspersed among them, they will be food for birds, and be the means of preventing them from destroying your finer fruit in the orchard or garden.

About six years ago, my worthy friend Walter Urquhart, Esq. of Warley Park, near Waltham Abbey, planted a clump of fruit and forest trees, with flowering shrubs in front, next the house, to screen his garden, which was so injudiciously situated as to present the walls to view from the house, and from almost every part of his beautiful park. The fruit trees made choice of for this purpose were large ones of various kinds, which had been

headed down, and were then full of fruit-buds. These trees were planted at a proper distance from the garden, so as not to shade the walls, and the forest trees interspersed among them, according to the height that they would attain when full grown.

Mr. Urquhart has continued to take up some of the forest trees from time to time, as the fruit trees spread their branches and require more room. Thus, the clump has become a nursery for forest trees; a great deal of money is saved which would otherwise have been expended in the purchase and carriage of plants; and from it he has made some very fine new plantations. The fruit trees make a handsome orchard, and at the same time cover the walls of the garden.

When the situation will not admit of such plantations, I would advise planting some cross-rows of fruit trees in the garden, at the distance of forty or seventy yards from each other, more or less, according to the size of the garden. In long rows, one row of trees will be sufficient on each side of the walk; but in the shorter cross rows, there should be two rows on each side. The trees should not be planted opposite to each other, but alternately; so as that those of one row may be opposite to the open spaces of the other. Trees planted in this manner will have a good effect, and will also serve to break the force of high winds, and prevent a great deal of damage, which might otherwise be done to the rest of the trees throughout the garden.

Those which I would recommend for the above purpose are dwarfs, with stems about two feet high, which can easily be obtained by cutting off the lower branches.

In laying out a new garden, another very essential point is, to make choice of a good soil. It should be two or three feet deep: but if deeper the better; of a mellow pliable nature, and of a moderately dry quality; and if the ground should have an uneven surface, I would by no means attempt to level it; for by that unevenness, and any little difference there may be in the quality, you will have a greater variety of soil adapted to different crops. The best soil for a garden is, a rich mellow loam; and the worst, a stiff heavy clay. A light sand is also a very unfit soil for a garden.

Sea-coal ashes, or the cleaning of streets and ditches, will be found very proper to mix with a strong soil; and if the ground should be cold, a large quantity of coal-ashes, sea-sand, or rotten vegetables, should be laid upon it, in order to meliorate and loosen the soil, and render it easy to work.

Lime rubbish, or light sandy earth from fields and commons, will also be found of great service to stiff clayey ground.

If the soil be light and warm, rotten neat's dung is the best dressing that you can give it. If horse-dung be ever used, it must be completely rotted, otherwise it will burn up the crop the first hot weather.

With regard to the form of a garden, there are various opinions, and it sometimes depends on the situation ; but where you are at perfect liberty I would prefer a square or oblong. As to the size, it may be from one acre to six or eight within the wall, according to the demand for vegetables in the family. It should be walled round with a brick wall from ten to twelve feet high : but if there be plenty of walling, which there may be when you are not stinted with respect to ground, I would prefer walls ten feet high, to those that are higher, and I am convinced they will be found more convenient. The garden should be surrounded with a border, or slip, from forty to sixty feet wide, or more, if the ground can be spared ; and this again inclosed with an oak paling, from six to eight feet high, with a cheval-de-frise \* at top, to prevent the people's getting over : it will also strengthen the paling.

By making slips on the outside of the garden wall, you will have plenty of ground for Goose-

\* A very good cheval-de-frise may be constructed as follows : Take a piece of wood of a convenient length, about four inches broad, and one inch and a quarter thick, and plane the upper edge into the shape of the roof of a house of a low pitch ; then draw a line on each side, from end to end, about an inch and a quarter below the upper edge, and through these lines drive twelve-penny nails, about four inches distant from each other, so as to come out near the upper edge on the opposite side. Each nail should be opposite the middle of the space between

berries, Currants, Strawberries, &c. You may allot that part of the slips which lies nearest to the stables, (if well sheltered, and exposed to the sun,) for Melon and Cucumber beds; and you can plant both sides of the garden-wall, which will give a great addition to the quantity of wall-fruit.

If the soil of the new garden be strong, it should be ploughed or dug three or four times before you plant any thing in it; and if it be thrown up in ridges during the winter, it will be of great service, as the frost will meliorate and loosen its parts.

Gardens, if possible, should lie near a river or brook, that they may be well supplied with water. From these, if the garden does not lie too high, the water may be conducted to it by drains, or, which is much better, by pipes, taking care to lay them low enough to receive the water in the driest season, which is the time when it will be most wanted.

If there be no running water near the garden, and if the latter lies on a declivity near a public road, I would advise to make a hollow drain, or a cut, from the most convenient part of the road, to receive the water that washes the road in rainy

---

two nails on the other side. The nail-heads should be sunk into the wood, and small strips nailed over them; then drive in tenterhooks between the nail-points, and nail the whole firmly on the outside of the top of the paling. In this manner proceed till you have finished the whole of the fence.

weather, and convey it to a large cistern, or tank, in the upper part of the garden; this, if the road be mended with lime-stone or chalk, will prove an excellent manure. The water from the cistern, or from the river, may be conducted to the different quarters by means of pipes, which having cocks at proper places, the water may be turned upon the different quarters of the garden at pleasure. Or the water may be conveyed in proper channels, and turned on the quarters in the same manner as in watering meadows.

These pipes, channels, &c. will be a considerable expence at first; but they will soon repay it by saving a great deal of time, which would otherwise be spent in pumping and carrying water. The most convenient time for turning the water on, is, in general, during the night: and in dry weather it would then be of the most essential service.

If the situation be such that you are obliged to pump the water from deep wells, there should be a large reservoir, in which it should be exposed to the sun and air for some days before it is used: it may then be turned on as above.

If the ground be wet and spewy, it will be proper to make a basin in the most convenient place, to receive the water that comes from the drains, and to collect the rain that falls on the walks.

In laying out the quarters, you must be guided in a great measure by the form and size of the garden; but do not lay them out too small, as in that case a great part of the ground will be taken up

with walks. The best figure is a square, or oblong, when the garden is of that form; but if not, they may be laid out in any other figure that is thought to be most convenient.

The middle walks should be about seven feet, which is wide enough to admit a cart; and the others about three or four feet broad; with a border on each side, five or six feet wide, at least, between the walk and the fruit trees. Walks in kitchen gardens are generally gravelled, and but seldom laid with turf, as the frequent wheeling and treading soon destroys the grass and renders them very unsightly; but a binding sand makes good walks, and they are easily kept; for when moss or weeds begin to grow, they may be cleaned with a horse-hoe, or scuffled over with a Dutch-hoe, in dry weather, and raked a day or two after, by which they will be made always to look neat and clean. I, however, give the preference to sea-coal ashes, which in my opinion make the best walks for a kitchen-garden, and they are easier kept than any other, being firm and dry, and cleaner to walk on than sand, especially after frost.

The bottoms of the walks should be filled up with brick rubbish, chippings of stones, or gravel and stones; those raked off the quarters will do very well, and by using them you will save carriage.

If the soil be stiff and wet, or subject to detain the moisture, there must be under-ground drains

made to carry off the water. In this case, let the main drain be made under the walk, to receive and carry off the water from those under the quarters. Draining, when the soil is wet, is absolutely necessary, otherwise the trees will never produce good well flavoured fruit, and your kitchen plants will be much injured: the drains also under the walks will keep them dry and firm, and make them fit for carting and wheeling on in wet weather.

The borders under the walls, in the inside, should be from ten to twenty feet wide, according to the size of the garden, to give full liberty to the roots of the trees to spread. There should be a footpath about two feet and a half from the wall, for the greater convenience of nailing the trees, gathering the fruit, &c. This walk should be from two to two feet and a half wide (to admit a barrow, or barrow-engine for watering the trees), and covered with sand, or, which is better, coal-ashes\*, about two or three inches thick; but without any gravel or rubbish below. On these borders you may have early or late crops, according to the aspect; but by no means plant any deep-rooting plants, such as cabbages, beans, peas, &c. (except early frame peas) which would be very hurtful to the trees.

\* Slugs avoid coal-ash walks, especially when new-laid and rough; such walks, therefore, may be of service, as they will, in some degree, obstruct the passage of slugs and snails from one quarter to another.

The reason for allotting part of the outside slip next the stable for hot-beds for raising Melons and Cucumbers, are, first, because there will be no litter to carry in within the walls to dirty the walks; secondly, the beds will not be seen from the garden; and, lastly, the convenience of carrying the dung, by which a great deal of time will be saved in carting and wheeling.

It will be necessary, especially in exposed situations, to enclose the Melon-ground with either a wall or paling from six to eight feet high. It was formerly a practice to enclose Melon-grounds with reed fences; but, although they are tolerably warm, and easily removed from one place to another (being made in separate pannels), they are very apt to harbour vermin.

Melons are best worked in brick-pits, coped with stone or oak, about twelve feet wide and two and a half deep: the length should be according to the number of frames that you work. The size of the lights, for early Melons, should be five feet long, and three broad: but for others they will require to be six feet long and four broad. The former should be four and the latter three light boxes. For the pits, a nine-inch wall will be sufficient: and if they are intended for a wood-coping, the bricklayer must build in some pieces of timber to fasten it to: but where stone can be had at a reasonable rate, I would give it the preference, as wood rots very soon.

There should be a walk between the ridges, about six or seven feet broad, sufficient to admit a cart to carry dung, which will be much more expeditious than wheeling. The walk should be made up as high as the coping, and sloping gently towards each end : the bottom should be filled up and covered as before directed ; this will be easily kept clean ; so that, after your linings are made up, it may be kept as neat as if it were in a pleasure-ground.

It will be necessary to make a loose drain along the middle of the bottom of the pit, to convey away wet, and the oozing from the dung, to a cistern, or tank, made on purpose to receive it. This moisture, which is the strength of the dung, may be used for watering Cabbage-plants, Cauliflowers, &c. or it may be thrown on the ground for manure. I have experienced it to be much better than dung.

When a garden is planted and finished, it will be found very convenient to have a plan of it, with the name of each tree inserted in its proper place. This I had done when the new slips were laid out in Kensington gardens, about ten or eleven years ago, and have found it of great service.

Walls of kitchen-gardens should be from ten to fourteen feet high ; the foundation should be two bricks or two bricks and a half thick ; the offset should not be above one course higher than the level of the border, and the wall should then set off a brick and a half thick. If the walls

are long, it will be necessary to strengthen them with piers from forty to sixty feet apart; and these piers should not project above half a brick beyond the wall. I do not approve of fixed copings, especially when they project so far as they are generally made to do; I would rather advise to have a moveable wooden coping, fixed on with iron hooks, fastened to pieces of wood built into the top of the wall; these copings would also be found very convenient to fasten the nettings, &c. to in Spring, for sheltering the fruit-trees. If, however, any should prefer fixed copings, they should not project above an inch on each side of the wall; this small projection will be sufficient to preserve the wall, and will not prevent the dew and rain from falling on the upper parts of the trees, which is of great service to them. Some copings are made of bricks, convex on the upper side; but I have lately seen a very good coping at Ashted Park near Epsom. It is made of a sort of Welch slate, to be had, of different sizes, at Mr. Samuel Wyatt's slate-yard, Christchurch, near Blackfriar's Bridge. This is made to project about one inch, and answers exceedingly well. Flat copings should have a little slope towards the North or East, according to the aspect of the wall; this will carry the wet from the South and West sides, which otherwise would be apt to injure the early blossoms and fruit on the South and West walls in cold nights.

When bricks can be had, I would advise never to build garden walls of stone; as it is by no

means so favourable to the ripening of fruit as brick. When a kitchen-garden contains four acres, or upwards, it may be intersected by two or more cross-walls, which will greatly augment the quantity of fruit, and also keep the garden warm, and shelter it greatly from high winds.

## CHAPTER XXIV.

## THE ORCHARD.

*Its Size, Situation, and Soil. — Choice of Trees, Preparing the Ground, Planting, &c. — An annual Wash for Trees.*

ORCHARDS are appropriated to the growth of standard fruit trees only where a large supply of fruit is wanted; and generally consist of Apple-trees, Pear-trees, Plum-trees, and Cherry-trees; but a complete Orchard should have, besides, Quinces, Medlars, Mulberries, Service-trees, Filberts, Spanish Nuts, and Barberries; as also Walnuts and Chesnuts; the two latter of which are well adapted for sheltering the others from high winds, and should, therefore, be planted in the boundaries of the Orchard, a little closer than ordinary, for that purpose. In choosing your trees, too much care cannot be taken to admit of none but such as have good roots, fair clean stems, and proper heads. In selecting your Pears and Apples, especially the latter, be careful to procure a proper assortment for the supply of your table during the whole year; a very few of the *Summer* sorts will suffice; more of the *Autumn*, and still more of the *Winter*, will be required; as upon this last you must chiefly depend for supply from

the month of January to July. See the *Method of preserving Fruit*, in CHAPTER XXV. p. 349.

In Cider-making counties, such as Hereford, Worcester, Gloucester, Somerset, and Devon, they have large Orchards of Apples; and in some counties (Kent in particular) there are Orchards wholly of Cherries. In general Orchards, however, there ought to be a much larger proportion of Apples than of any other fruit. Orchards, in proper situations, are very profitable; beside, the trees have a delightful appearance when in blossom, and also when the fruit is ripe.

What has been said respecting the situation and soil of a Garden is also applicable to an orchard. The situation of an orchard should be rather elevated than low; on a gentle declivity; and open to the South and South East, to give free admission to the air and rays of the sun (to dry up the damps and disperse the fogs), which will render the trees healthy, and give a fine flavour to the fruit. An Orchard should also be well sheltered from the East, North, and Westerly winds, by plantations, if not naturally sheltered by rising grounds. These plantations of forest-trees should neither be too large nor too near the Orchard: as they would in that case prevent a free circulation of the air, which would prove injurious to the fruit-trees. But, if the ground will not admit of such plantations, I would advise planting cross rows of fruit trees, as directed for gardens. I would also recommend planting some

of the largest growing trees nearest the outsides exposed to those winds; two or three rows of which should be planted closer than ordinary, which would greatly shelter those in the interior parts of the Orchard. Walnut and Chesnut-trees, as has been already observed, are well adapted for this purpose.

As to the size of an Orchard, it may be from one to twenty acres, or more, according to the quantity of fruit wanted, or the quantity of ground that you may have fit for the purpose.

That soil which produces good crops of corn, grass, or garden vegetables, will also do for an Orchard; but a loamy soil is to be preferred; though any of a good quality, not too light or dry, nor wet, heavy, or stubborn, but of a moderately soft and pliant nature, will be found to answer the end. Shingly and gravelly soils disagree very much with fruit-trees, unless there be loam intermixed.\* They will succeed much better on a chalk bottom. On such a soil, I have seen roots twelve feet deep, and trees thrive well. If the bottom be clay, the roots should be cut-in once

\* Where no better is to be had, the holes should be dug at least three feet deep, and filled up with good mould: if mixed up with rotten dung, rotten leaves, or other manure, the trees will in time amply repay the expence: the dung used for this purpose should be that from the Melon and Cucumber beds, mixed with the mould from the same, when the beds are broken up in Autumn or Winter; it should be laid up in heaps, and continue so for one year at least; but should be frequently turned, and have some good fresh mould mixed with it.

in four years, to prevent them from penetrating the clay, which would greatly injure the trees. The soil should be from two to three feet deep; before planting the trees, it should be trenched two spits deep, and ten feet broad where the rows are to be planted, and a spit below loosened, unless it be clay, which should be trodden down. If it be pasture ground, it should be ploughed, and well summer fallowed, till the grass be killed: otherwise, when it is laid in the bottom in trenching, which it generally is, it will be very apt to breed grubs, which will do much mischief.

Some only dig holes large enough to receive the roots, especially in grass ground which is to be continued so. Others prepare the ground by deep ploughing, if the orchard is to be of great extent. The sward, if pasture, should be ploughed in some time in Spring: give it a good summer fallow, in ploughing it two or three times, which will rot the turf. A fortnight or three weeks before planting, give the ground a good deep ploughing, to prepare it for the reception of the trees. The best time for planting on a dry soil is in October; but if wet, the latter end of February, or the month of March, will be a fitter season.

In planting, endeavour to suit the trees as well as possible to the soil, and to plant them at proper distances from each other; which may be from forty to eighty feet, according to the size of the trees when full grown. Fruit trees, as has already been observed, when planted too thick, are very

liable to blights, and to be covered with moss, which robs the tree of a great part of its nourishment, besides spoiling the flavour of the fruit. Procure your trees from a soil nearly similar to, or rather worse than that where you intend to plant them; for trees transplanted from a rich soil to a poorer never thrive well, but if from a poorer to a richer soil, they will generally succeed.

If trees are planted in the quincunx order, and at the distance of eighty feet, the ground between the rows may be ploughed and sown with Wheat, Turnips, &c. or planted with Potatoes. Ploughing or digging the ground, provided it be not done so deep as to hurt the roots, by admitting the sun and rain to meliorate the ground, will keep the trees in a healthy flourishing state. It will be necessary to support the young trees by tying them to stakes until they are well rooted, to prevent their being loosened or blown down by the wind. The Spring after planting, if it proves dry, dig up some turf, and lay it round the stem of the young trees with the grassy side downwards; this will keep the ground moist, and save a deal of watering; if the trees have taken well, this need not be repeated, as they will be out of danger the first year. The turf should be laid as far as you think the roots of the trees extend; and when it is rotted, it should be dug in, which will be of great service to them.

Trees that are of very different sizes when full-grown should not be planted promiscuously: but,

if the soil be properly adapted, plant the larger in the back part or higher ground, or at the North-ends of the rows, if they run nearly North and South, and the others in succession according to their size. Fruit trees planted in this manner will have a fine effect when grown up; but if they are planted promiscuously, they will not appear so agreeable to the eye; and, besides the smaller trees will be shaded by the larger, which will injure them, and spoil the flavour of the fruit.

Orchards should be dunged once in two or three years. The stem of trees in those where cattle feed should be high enough to prevent their eating the lower branches; and fenced in such a manner as to prevent their being barked, or injured, by the cattle rubbing against them, particularly when young; which may be done by triangles of wood, or the trees may be bushed with thorns, &c. The trees are to be pruned and managed as already directed for Apples, Pears, Plums, &c. &c.

If the soil be wet, it must be drained, as already directed for a garden. When the surface of the ground is wet, and has a little descent, it may be formed into a kind of ridges, by making a furrow, from one to two feet deep, between every two rows, sloping the ground regularly on each side, from a reasonable distance to the bottom of the furrow. These hollows will carry off the water, and render the surface dry and healthy. If pasture, the turf may be first pared off, and afterwards re-laid when the furrow is made.

In orchards, where cattle are not permitted to go, I would prefer dwarf-trees to standards, taking care to proportion the distance of the rows to the size of the trees. But in orchards kept for pasture, it will be necessary to plant standards.

Burning of rotten wood, weeds, potatoe haulm, wet straw, &c. on the windward side of the trees when they are in blossom, will be found a good preservative from blights, caterpillars, &c.

I would recommend washing the trees annually, in the month of February or March, with the following mixture, which will destroy the eggs of insects, and prevent moss from growing on the trunks and branches: it will also help to nourish the tree, keep the bark fine and healthy; and will have the same effect on it as a top dressing has upon grass land.

Mix fresh cow-dung with urine and soap-suds, and with this mixture wash over the stems and branches of the trees, as a white-washer would wash the ceiling or walls of a room; taking care to cut off all the cankerous parts, and to scrape off all the moss, before you lay the mixture on. In the course of the Spring or Summer, you will see a fine new bark coming on. When the old bark is cankerous, you must pare it off with a draw-knife, or such a long knife as I have had made on purpose, especially for wall-trees, where the draw-knife cannot be applied, next the wall. The knives and other tools for dressing decayed trees will be de-

scribed hereafter. \* When you see it necessary to take all the outer bark off, you must cover the stem, &c. with the Composition and powder, patting it gently down, as in the case when large limbs are cut off.

If the above wash be repeated in Autumn, after the fall of the leaf, it will destroy the eggs of a great many insects that hatch in Autumn and Winter. This washing will be found of great service to all kinds of fruit and forest trees whatever.

\* See Plate XIII.

## CHAPTER XXV.

## OF GATHERING APPLES AND PEARS.

*The Time and Manner of Gathering them ; and of the Management of the Fruit-room. — Of Packing Fruit for Carriage.*

As Apples shaken or beaten down with a pole never keep in Winter, they ought all to be hand-picked by a person standing on steps made on purpose.

The steps should be light, for convenience of moving from one place to another ; and so contrived, that the ladder may be disengaged from the back at pleasure ; which may easily be done if they are fastened together by a bolt at top. There should be a broad step at top to stand on, with room for the basket which is to hold the fruit. When you begin to gather the fruit, you should be provided with hand baskets of different sizes, and also with large baskets, or hampers, and wheelbarrows. You must lay some short-grass mowings, perfectly dry, (which you ought to provide for the purpose in Summer, and keep in a shed or any other dry place till wanted) at the bottoms of the large baskets and hampers, to prevent the fruit from being bruised.

Observe attentively when the Apples and Pears are ripe ; and do not pick them always at the same regular time of the year, as is the practice with

many. A dry season will forward the ripening of fruit, and a wet one retard it; so that there will sometimes be a month or five weeks difference in the proper time of gathering. The method that I have practised is, to observe when the fruit begins to fall (I do not mean what we call wind-falls, or the falling of such as are infested with the caterpillar, &c.), but sound fruit; I then put my hand under it; and if it comes off without any force being used, I take it for granted that the fruit is perfectly ripe; unless the tree be sickly, which is easily known by the leaves or fruit being shrivelled. If the foregoing observations are attended to, the fruit will keep well, and be plump; and not shrivelled, as is the case with all fruit that is gathered before it is ripe.

The person on the steps should pick the fruit carefully, and lay it gently into the basket on the top of the steps; for if it be in the least bruised, it will not keep. For the same reason, great care must be taken in emptying the fruit out of the hand-baskets, when full, into the large baskets or hampers. If more than one large basket be wheeled at once, which may generally be done, the lower ones must not be so full as to let the bottom of the upper one touch the fruit; it will also be necessary to put some of the soft dry grass between the baskets, and also over the fruit in the upper basket.

When the fruit begins to fall of itself, cover the ground under the tree with some of the short

grass mowings, or if that cannot be procured, with some pease-haulm, or oat or barley straw, quite dry: this will preserve the fruit from bruising when it drops; the fruit which thus falls of itself should be laid up separate from, and used before, that which is hand-picked, according to the season in which they are fit to be sent to table. Should any be bruised by falling on one another, they should be thrown aside, as only fit for baking, or to be given to the pigs.

When all the fruit is gathered in, rake off the short grass, &c. and throw it up to rot, or mix it with dung, or leaves of trees; for, if it remain on the ground during the Winter it will harbour slugs.

When the bolt of the steps is taken out, and the ladder and back part separated, the ladder will then be fit to use in gathering fruit off wall trees; only it will be necessary to screw on the upper part of it two pieces of iron, or nail two pieces of ash or oak, about six or eight inches long, to keep it far enough from the wall to prevent the tree from sustaining any damage in the bark or branches; which would infallibly bring on the canker.

When the fruit is carried to the fruit-room, lay some of the dry short grass on the floor, in the area of the room; then take the fruit gently out of the baskets, and lay it in heaps on the top of the grass, keeping each sort in a separate heap; the heaps may be from two to three feet high, or according to the quantity of fruit that you have. When the

heaps are completed, cover the tops at least two inches thick with short grass, in order to sweat them. Let them lie a fortnight, then open the heaps and turn them over, wiping each Apple or Pear with a dry woollen cloth, which should be frequently dried during the process, observing now to lay in the middle the fruit which before was at the top. Let the heaps now remain eight or ten days, covered as before; by that time they will have thrown out the watery crudities which they may have imbibed during a wet season; then uncover the heaps, and wipe the fruit carefully one by one, as before, picking out every one that is injured, or has the least spot, as unfit for keeping.

Fruit should be gathered, if possible, in dry weather, and when the dew is exhaled from off the trees; and remember never to gather in the evening after the dew begins to fall.

During the time that the fruit is sweating, the windows should be left open, except in wet and foggy weather, to admit the air to carry off the moisture which perspires from the fruit. The perspiration will sometimes be so great, that on putting your hand into the heap, it will come out as wet as if it had been dipped into a pail of water: when in this state it will be necessary to turn and wipe the fruit.

In laying up fruit the common practice has been to lay it on clean wheat-straw; but I find by experience, that when any of the fruit begins to decay, if it be not immediately picked out, the

straw, by imbibing the moisture from the decayed fruit, will become tainted, and communicate a disagreeable taste to the sound fruit.

I would likewise caution those who erect new shelves in their fruit-rooms, to have the timber well seasoned, and to make use of white deal in preference to red, as the latter, especially if not very well seasoned, is apt to give a very disagreeable resinous taste to the fruit, which quite spoils its flavour. I would, therefore, recommend covering the bottoms of the shelves with thin coarse canvass, (such as may be purchased for about eight or ten pence a yard,) on which the fruit should be laid in a single layer, after being wiped very dry; but by no means lay them a-top of one another. When that is done, cover them with a piece of the same canvass, or thin flannel, or with old newspapers, or whitish brown paper, which will in a great measure exclude the air, prevent the frost from injuring the fruit, and preserve a beautiful smoothness on its skin. The fruit should be turned two or three times during the Winter; as delicate and tender fruit, by lying long without turning, is apt to rot on the underside, even if perfectly sound when laid up. Be particularly careful, however, to pick out all the damaged fruit.

When the fruit is laid in, put the earliest sorts on the lower shelves, or in the lower drawers, according to their time of coming in, beginning with the Nonsuch, Golden Rennet, and Jenneting Apples, and Bergamot and Beurré Pears (for I find by ex-

perience, that the Jargonelle keeps best on the tree, as, if gathered, it rots almost immediately); thus, by proper management, you may have a constant succession of fruit from one season to the other.

When there are large quantities of fruit, it will require a great deal of time to lay it on the shelves, &c.: this business may therefore be done in wet weather, or in the evenings, when you cannot conveniently spare your men from the out-door work in the day time.

Those who keep their fruit in store-houses, for the supply of the London and other markets, as well as those who have not proper fruit-rooms, may keep their Apples and Pears in baskets or hampers; putting some soft paper in the bottoms and round the edges of the baskets, &c. to keep the fruit from being bruised; then put in a layer of fruit, and over that another layer of paper; and so on, a layer of fruit and of paper alternately, till the basket or hamper be full: cover the top with paper three or four times double, to exclude the air and frost as much as possible. Every different sort of fruit should be packed separately; and it will be proper to fix a label to each basket or hamper, with the name of the fruit that it contains, and the time of its being fit for use.

But the best way of keeping fruit is, to pack it in glazed earthen jars. The Pears or Apples must be separately wrapped up in soft paper; then put a little well-dried bran in the bottom of

the jar, and over the bran a layer of fruit; then a little more bran to fill up the interstices between the fruit, and to cover it; and so on, a layer of fruit and bran alternately, till the jar be full; then shake it gently, which will make the fruit and bran sink a little; fill up the vacancy at top with more bran, and lay some paper over it, covering the top with a piece of bladder to exclude the air; then put on the top or cover of the jar, observing that it fits as closely as possible. These jars should be kept in a room where you can have a fire in wet or damp weather.

*Of packing Fruit for Carriage.*

If fruit be to be sent to any considerable distance, great care should be taken in packing it: which should not be in baskets, as they are liable to be bruised among heavy luggage, and the fruit, of course, will be injured. I would, therefore, recommend boxes made of strong deal, of different sizes, according to the quantity of fruit to be packed. The following are the dimensions of the boxes in which we send fruit by the coach to Windsor and Weymouth, for the use of His Majesty and the Royal Family; viz.

The larger box is two feet long, fourteen inches broad, and the same in depth. The smaller box is one foot nine inches long, one foot broad, and the same depth. These boxes are made of inch deal, and well secured with three iron clamps at each

corner : they have two small iron handles, one at each end, by which they are fastened to the roof of the coach : in these boxes we send Melons, Currants, Pears, Peaches, Nectarines, Plums, and Grapes, packed so as always to have the heaviest fruit at bottom. The melons are wrapped up in soft paper : the Pears, Peaches, Nectarines, Plums, and Grapes, are first wrapped up in Vine-leaves, and then in paper. The Cherries and Currants are packed in a flat tin box, one foot four inches long, ten inches broad, and four deep.

In packing, proceed thus : — First, put a layer of fine long dry moss in the bottom of the tin box, then a layer of Currants or Cherries, then another layer of moss ; and so on, alternately fruit and moss, until the box is so full, that, when the lid is hasped down, the fruit may be so firmly packed as to preserve them from friction.

Make a layer of fine moss and short soft dry grass, well mixed, in the bottom of the deal box ; then pack in the Melons with some of the same, packing it tight in between all the rows, and also between the Melons in the same row, till you have finished the layer ; choosing the fruit as nearly of a size as possible, filling up every interstice with the moss and grass. When the Melons are packed, lay a thin layer of moss and grass over them, upon which place the tin box with the Currants, packing it firmly all round with moss to prevent it from shaking ; then put a thin layer of moss over the box, and pack the Pears firmly (but so as not to

bruise them) on that layer, in the same manner as the Melons; and so on with the Peaches, Nectarines, Plums, and lastly, the Grapes, filling up the box with moss, that the lid may shut down so tight as to prevent any friction among the fruit. The boxes should have locks, and two keys, which may serve for them all; each of the persons who pack and unpack the fruit having a key.

The moss and grass should always be returned in the boxes, which, with a little addition, will serve the whole season, being shaken up and well aired after each journey, and keeping it sweet and clean. After the wooden box is locked, it will be necessary to cord it firmly.

My reason for being so particular on packing of fruit is, that I have known instances of its being totally spoiled in the carriage from improper packing.

By pursuing the above method we have never failed of success; and if fruit be packed according to the foregoing directions, it may be sent to the farthest parts of the kingdom, by coaches or wag-gons with perfect safety.

## CHAPTER XXVI.

## OF THE CANKER, AND GUM.

*A Description of the Canker; its Origin and Progress.— Full Directions for Curing it. — Of the Gum and its Remedy.*

**T**HE Canker is a disease incident to trees, which occasions the bark to grow rough and scabby, and turns the wood affected to a rusty brown colour. This disease, if no remedy be applied, will in time totally kill the tree.

Apple-trees are very liable to be infected with the canker from the following causes, viz.

From injudicious pruning, from the foot-stalks of the fruit being left on the trees, and from injuries sustained by applying ladders in gathering the fruit; these injuries are very hurtful to the trees, and will infallibly bring on the canker when no remedy is applied. A man ought to stand on steps, instead of a ladder, when the fruit is out of his reach from the ground. Care should also be taken in nailing, that the shreds be not too tight, which causes a swelling in the shoot, and very often produces the canker.

Another cause of the canker is, when we have very wet Autumns, such as that of 1799, which prevents the young wood from ripening, and a

hard frost setting in after it kills the young shoots : these, if left on the tree, will bring on the canker, and increase it rapidly. Birds and insects devouring the buds will have the same effect.

Careless people frequently leave the dead shoots on the tree throughout the Summer, which will infallibly bring on the canker. Some even leave them for years, until the tree is totally killed. They should be cut off in the end of April, or beginning of May ; as by that time you will be able to see how far the disease has advanced. I would advise to cut two or three buds, or even more, below the apparently diseased part, as the canker frequently reaches a great way farther in the heart of the shoot than it appears to do on the outside : you must cut down till the brown colour in the shoot disappears, and nothing remains but sound white wood.

The truth of the foregoing observations will appear evident to any person who takes notice of the Apple-trees with their mutilated stag-looking heads, as he rides or walks along the road.

It is a general opinion, that the canker in all trees proceeds from the nature of the ground in which they are planted ; such as a sour clay, a shingly or gravelly soil, &c.

My late and much-esteemed friend Mr. Hudson, author of the “*Flora Anglica*,” was of this opinion, till I convinced him of the contrary by some experiments made at Nutwell, near Exeter, the seat of the late Sir Francis Drake, a gentleman

very fond of gardening and agriculture. Mr. Hudson said, it would be to no purpose to make any attempt to cure the Apple-trees, as the ground was of such a nature as to bring on the canker. The trees were, indeed, in a sad condition, being covered all over with lichens and moss, and very much infected with the canker. I requested Mr. Hudson to fix on some of the worst; we then desired the gardener to open the ground round their roots, which we found perfectly sound, the bark of them smooth, and not the least appearance of the canker to be seen.

The canker, as before observed, proceeds from bruises in the bark, from limbs cut off, &c. When these limbs begin to rot and grow hollow, they convey the canker to the root; for it always proceeds from the branches and stem to the roots, and never from the roots to the tree.

It is granted, however, that all fruit-trees love a fine rich mellow loam, and thrive much better in it than in a shingly or gravelly soil.

When by accident, or improper treatment, trees receive large wounds, and the cure is left to nature, they are frequently over-run with gum and canker, which, if not checked, will in a short time totally ruin them.

In this case you must carefully pare off, with a draw-knife, or any other convenient instrument, all the diseased part of the bark. The inner white bark is frequently infected; this must also be cut away till no appearance of infection remains.

The infection in the inner bark appears like dots made with a pen, all of which must be cut clean out; for if any part of the canker be left, it will infect the new wood and bark. Wherever you see gum oozing out, you may rest assured that the canker is not quite eradicated; which, if suffered to remain, will spread till the whole tree becomes a mass of gum and canker, and will be killed in a very short time.

When the trunk is become hollow, cut the loose rotten part clean out till you come to the sound wood, taking care to round the edges of the hollow part; then apply the Composition in a liquid state, laying it on with a painter's brush, wherever the cankered bark has been pared off or the dead wood cut out, till these places are entirely covered with it: when that is done, shake some of the powder of wood-ashes and burnt bones over the Composition, and pat it gently down with your hand. See DIRECTIONS FOR THE MAKING AND LAYING ON OF THE COMPOSITION, p. 453.

If the foregoing directions be carefully followed, the canker will be completely eradicated, and the hollow trunk in time be filled up with sound wood.

When the stem is much decayed, it will be absolutely necessary to open the ground, examine the roots, and cut off all the rotten parts. When you have cut out all the rotten and decayed parts below ground, and scraped the hollow clean, make

up a mass of the Composition mixed with some clay, like what is used for grafting; then fill the hollow part with it to within about two inches of the surface of the ground, treading it in with your foot, or pressing it in with the hand, as close as you possibly can, to prevent the wet from penetrating to the roots, and leave the surface of the Composition sloping from the tree towards the outside of the border, to throw the wet off, which will prevent the fresh part of the root from rotting; then cover the root over with mould, level with the rest of the border.

When you have examined all the old wounds where large limbs have been cut off, you should next examine the old bark; and, if you find the outside of it wrinkled and cracked, pare it off, as it is always, when in that state, very much hurt by the canker. This should be done with the draw-knife, or other sharp instrument; then apply the Composition as before directed, which will bring on a fine smooth bark under it. In the succeeding Winter, or Spring, you will see all the plaster, with the old part of the bark that was left in the hollow parts of the tree, or where old branches had been amputated, peeling off and showing the smooth bark underneath. You should then scrape off, with a wooden or bone knife, what old bark remains in the hollows where the draw-knife could not reach without cutting too much away. When that is done, mix up some fresh cow-dung with soap-suds and urine, making it very

thin, and give the tree a coat of this mixture all over where the bark has been scraped off; the cow-dung will adhere to it, and heal the parts where you were obliged to scrape to the inner bark. This wash will remain till the fresh bark comes on; then it will be discharged of itself during the Summer, or the next Spring, leaving a new fresh smooth bark where the old and cankerous was taken off. Next Spring, if any of the old bark remains, you may repeat the same operation, which will cause all the remaining old bark to slough off like a scab from a wound on the human body.

By these means you will keep your trees in a fine flourishing healthy state, and, in general, prevent them from becoming bark-bound. If any of them, notwithstanding, should be bark-bound, you may scarify them, by taking a sharp knife, and running the point of it straight down the middle of the stem from top to bottom; taking care to run your knife through the outer bark only, then, with a brush, or your finger, rub in some of the Composition, to prevent the incision from bringing on the canker. This operation will cause the tree to expand the bark and become very flourishing.

Remember to cut off all the ends of the small shoots where the canker had injured them last year. Cut off also the old fruit-stalks, and all the small dead stubs, which, if left, will never fail to bring on the canker.

The rough or cankered bark on that side of trees which is next the wall should be scraped or pared off with a tool made in the form of a sickle, which, with other tools, will be described hereafter.

It is much to be regretted, that fruit trees in general throughout this kingdom are in a mutilated unfruitful state. After gentlemen have purchased the young trees from Nurseries, and planted them in their orchards and gardens, they think every thing necessary is done; when, in fact, the greater part of the work is yet to come. In packing and carriage, the stems and branches are very frequently bruised; in that case, the injured parts of the bark and wood must be carefully cut out, and the Composition immediately applied: this may be done when you head the trees, which operation should be performed in April, May, or even June, when the bud begins to shoot; but by no means cut off any of the shoots, except those that are broken or bruised very much. When this is neglected, the canker will follow, to the great injury, if not the death, of the trees. How common is it to see, in all parts of the country, great numbers of trees so affected with this disease as not to produce fruit enough in twelve or fourteen years to pay half the expence attending them! whereas, if they were to be managed according to the foregoing directions, they would more than pay all the expence in three years. It is common, when young trees do not thrive, either to blame the nurseryman for sending bad or diseased trees, or at-

tribute their unthriving state to the nature of the soil; whereas the fact is, that this frequently arises from the inattention or mismanagement of the person who plants and superintends them. If the injured and diseased parts be not cut out at an early period, the trees will not thrive, but will become cankerous and stunted, and cannot be recovered afterwards without a great deal of labour and trouble; whereas, if the directions given for heading trees the first year, and cutting out the diseased parts, be attended to, the trees will flourish, and bear large crops of fine and well-flavoured fruit.

*The Gum.*

The Gum is a kind of gangrene incident to fruit trees of the stone kind, and arises from the following causes: from injudicious pruning, from bruises, or any injuries received in the wood or bark. This may happen from strokes of the hammer in nailing, from pinching the shoots by nailing the shreds too tight, or by driving the nails too close to the branches. It may also be occasioned by leaving the foot-stalks of the fruit, or by pruning in Summer, and cutting the shoots to short stumps, and by injuries sustained by a careless application of ladders in nailing and gathering the fruit, &c. but it particularly originates where large limbs have been lopped or broken off. This disease may be known before the gum itself makes its appearance. The bark at first becomes of a brownish colour,

which gradually grows darker, till at last the gum begins to ooze out like little blisters. As soon as any of these symptoms are observed, the infected parts should be cut out with a sharp instrument, and the Composition and powder applied immediately. You must observe to cut out the gum perfectly clean; you will see it oozing out from between the wood and bark: this must be followed till you come to the white clean bark and wood. If afterwards any gum should make its appearance, it must be scraped off; which is best done when it is moistened with rain, as you can then scrape it off easily without hurting the bark. This must be done without delay, otherwise the disease will rapidly advance.

When trees are hollow, it will be necessary to examine them carefully to see whether any grubs have entered the bark and wood, which you will know by their perforating the bark. If there be any, they must be carefully cut out before the Composition is applied.

## CHAP. XXVII.

## OF THE MILDEW, HONEY-DEW, AND BLIGHTS.

*A Description of the Mildew, and the Remedy for it. — Of the Honey-dew and its Remedy. — A Description of different Sorts of Blights, and the best Means of preventing them.*

*Of the Mildew.*

THE Mildew, a disease very hurtful to plants, is a kind of thick clammy moisture, which falls on, or rather transpires from the leaves and blossoms of plants. This clammy substance, by stopping up the pores, prevents perspiration, and hinders the growth of the plant. But what is commonly called mildew is an insect which is frequently found in vast numbers feeding upon this moisture. Mr. T. S. Segar, in a treatise upon this subject, says, that the mildew is of a very sharp corrosive nature, and by its acrimony hinders the circulation of the nutritious sap; in consequence of which the leaves begin to fade, and the blossoms and fruit are greatly injured.

I have observed that, contrary to the common opinion, trees are more liable to mildew on South and West walls, than on an East wall; and I have frequently removed such trees from a South or

West wall, to a North or East wall, where they have perfectly recovered.

Whenever you apprehend danger, wash or sprinkle the trees well with urine and lime-water mixed ; and when the young and tender shoots are much infected, it will be necessary to wash them well with a woollen cloth dipped in the following mixture, so as to clear them of all the glutinous matter, that their respiration and perspiration may not be obstructed.

Take tobacco one pound, sulphur two pounds, unslaked lime one peck, and about a pound of elder buds ; pour on the above ingredients ten gallons of boiling water ; cover it close and let it stand till cold ; then add as much cold water as will fill a hogshead. It should stand two or three days to settle : then take off the scum, and it is fit for use.

#### *Of the Honey-dew.*

The Honey-dew is a sweet saccharine substance found on the leaves of certain trees, and is generally supposed to fall from heaven like dew ; but this is a mistaken opinion. One kind of honey-dew transpires from the leaves of the trees where it is found : and the other is the excrement of a small insect called a vine-fretter, a species of *Aphis*. Bees and ants are very fond of both these kinds of honey-dew.

As the honey-dew, by its viscous quality, closes

up the pores, and stops the perspiration of trees, it must of course be very hurtful to them. This disease should be treated in the same manner as the mildew; but, as has already been observed, trees should be watered, or washed, early enough in the day to get dry before the cold of the night comes on; nor should it be done while the sun shines very hot, which would be likely to scorch the blossoms and leaves.

*Of Blights.*

Blights are very destructive to fruit-trees, sometimes destroying the whole tree; but more frequently the leaves and blossoms, while the tree itself remains unhurt.

One cause of the blight is, the continuance of a dry easterly wind for several days together, which stops the perspiration in the tender blossom; and a long continuance of the same weather equally affects the tender leaves, causing them to wither and decay; the perspiring matter is thereby rendered thick and glutinous, and so becomes food for those small insects which are always found in vast numbers on fruit trees that are affected by this sort of blight.

These insects, however, are not the original cause, as some imagine, but the natural consequence of blights; for wherever they meet with such a proper nutriment they multiply amazingly,

and greatly promote the distemper when no method is taken to prevent it.

The best remedy for this distemper that I know of is, to wash them with urine and soap-suds, as before directed; and the sooner this is performed, whenever we apprehend danger, the better: if the young and tender shoots seem to be much infected, wash them with a woollen cloth dipped in the same liquid that is recommended for the mildew.

Another cause of blights in the Spring will be found in sharp hoary frosts, which are often succeeded by hot sunshine in the day-time; these are certain and sudden destruction to the fruit. Sharp pinching frosty mornings, which often happen when the trees are in flower, or while the fruit is very young, occasion the blossoms or fruit to drop off, and sometimes greatly injure the tender shoots and leaves.

The only method yet found out to prevent this mischief is, the carefully covering the walls with netting, &c. as before directed.\* The covering is to remain on during the night, and to be taken off in the day-time. This method has been reckoned of little service by some, which, indeed, may be the case when the coverings are not properly used; for, if the trees are kept too long covered, the young branches and leaves will be so weak as not to be able to bear the open air when they are exposed to it.

\* P. 11, 12. 62.

The same consequences will follow when the trees are incautiously exposed to the air after having been long covered.

But if the covering be properly performed, it will frequently preserve the fruits under it, when there happens almost a general failure in the neighbourhood where this precaution has been neglected. The great trouble which seems to attend it may deter many from putting it in practice; yet if the nettings, or other coverings, be so contrived as to draw up and let down by means of pulleys, the business may be done with ease and expedition; and the success attending it will make ample amends.

But what is called a blight is frequently no more than a weakness or distemper in trees. This is the case when trees against the same wall, and enjoying the same advantages in every respect, differ greatly in their health and vigour, the weak ones appearing to be continually blighted, while the others remain in a flourishing condition. This very great difference, in such circumstances, can be attributed only to the different constitutions of the trees, proceeding from a want of proper nourishment, or from some bad qualities in the soil, some distemper in the stock, buds, or scions, or from mismanagement in the pruning, &c. all of which are productive of distempers in trees, of which they are with difficulty cured.

If the fault be in the soil, it must be dug out, and fresh mould put in its place; or the trees must

be taken up, and others better adapted to the soil planted in their room. It will be found absolutely necessary always to endeavour to suit the particular sorts of fruits to the nature of the soil; for it is in vain to expect all sorts of fruit to be good in the same soil.

If the weakness of the tree proceed from an inbred distemper, it will be adviseable to remove it at once, and after removing the earth to plant another in its place.

But if the weakness has been brought on by ill-management in the pruning, which is frequently the case, I would advise the method of pruning and training which is laid down in this treatise to be adopted without loss of time.

How common it is to see the young luxuriant branches trained up to their full length every year, and so carried to the top of the wall in a very short time, by which the fruit-bearing branches are robbed of a great part of their nourishment, which weakens them so much that they have not strength to produce fruit; but the blossoms fall off, and not unfrequently the branches decay, sometimes even their whole length, and this is ascribed to a blast! Luxuriant shoots should be stopped; and all superfluous wood should be cut out; otherwise they will exhaust a great part of the nourishment which should go for the support of the fruit-bearing branches.

There is another sort of blight that sometimes happens pretty late in the Spring, viz. in April and

May, which is very destructive to fruit trees in orchards and open plantations, and against which we know of no effectual remedy. This is what is called a fire-blast, which in a few hours hath not only destroyed the fruit and leaves, but often parts of trees, and sometimes entire trees have been killed by it.

This is generally thought to be occasioned by certain transparent flying vapours, which may sometimes take such forms as to converge the sun's rays in the manner of a burning-glass, so as to scorch the plants they fall upon, and this in a greater or less degree in proportion to their convergency. As this generally happens in close plantations, where the vapours from the earth, and the perspirations from the trees, are pent-in for want of a free circulation of air to disperse them, it points out to us the only way yet known of guarding against this enemy to fruits; namely, to make choice of a clear healthy situation for kitchen-gardens, orchards, &c. and to plant the trees at such a distance as to give free admission to the air, that it may dispel those vapours before they are formed into such volumes as to occasion these blasts.

But blasts may also be occasioned by the reflection of the sun's rays from hollow clouds, which sometimes act as burning mirrors, and occasion excessive heat. Against this there is no remedy.

## CHAPTER XXVIII.

## OF INSECTS, &amp;c.

*Of the Different Sorts of Insects infesting Fruit-Trees, and the Method of destroying them. — How to preserve Fruit from Birds ; and of destroying Rats and Mice.*

*Of the Aphis.\**

**A**PHIDES, or Plant-lice, are a very numerous and destructive tribe of insects. Entomologists enumerate seventy-five species of them ; but probably there are many more, as every tree infested by them has a distinct species ; and Linnæus names them from the different trees that they live upon ; as the currant aphis, the plum aphis, the cherry aphis, &c. &c. The males, which are very few in comparison of the females, have wings ; but the females are apterous, or without wings.

Aphides are devoured by the larva of the Myrmeleon Formicarius, or ant-eater, of Linnæus.

\* Those who wish for farther information respecting insects, may consult Reaumur's History of Insects, or Dr. Anderson's Recreations in Agriculture, Natural History, &c. &c.

Ants are likewise very fond of them, on account of a sweet liquid which they eject from the anus. Aphides are extremely common.

Fruit trees are frequently very much infested with different species of the aphis; the Plum, in particular, suffers greatly by them. Those which I have most frequently found on Plums, are, the brown, the green, and the light sea-green aphis; but as before observed, different sorts of trees generally have different species of aphides. Great care should be taken to destroy these pernicious insects at as early a period of their growth as possible; otherwise they will consume the leaves and fruit for that season. The best method that I have found for this purpose is, to take some fine wood-ashes mixed with one-third part of fine unslaked lime, and throw it on with a common dredging-box, till you have covered the undersides of all the leaves where you find the insects: this should be done in the morning early, while the dew is on the leaves, which will cause the powder to adhere to them; letting them remain so covered with the powdered lime for three or four days. Then mix unslaked lime and soft water, or water that has been exposed to the sun a week at least, at the rate of half a peck to thirty-two gallons, and stir it well two or three times a day, for three or four days. If you have many trees that are infected with insects, mix up a large quantity in the same proportion as the above. I generally mix as much at

once as will fill a cistern \*, about seven feet long by three and a half broad, and three feet deep, and that contains about 550 gallons, which, according to the foregoing proportion, requires about two bushels and half a peck of lime. With this liquid, after the lime has subsided, give the trees a good watering, observing to throw a considerable part of it under the leaves, by a barrow-engine ; this should be repeated once a day, for six days, which will destroy all the aphides. The engine that I would recommend, is that of the late Mr. Winlaw's construction, which may be had of Messrs. Chieslie and Yowle, No. 72, Margaret-Street, Cavendish-Square. (1802.)

If you find the insects begin to make their appearance again, apply the powder as before directed, and repeat the watering.

*Particular Directions for using the Lime-water.*

Take the clear water after the lime has settled, fill the engine with it, and give the trees a good watering; throwing it with as much force as you can under the leaves ; pressing your fore-finger over the mouth of the pipe to spread the water like the falling of small rain, which you may very easily do, at the same time wheeling the engine back-

\* If it be a leaden cistern, a little loam, enough to cover the bottom, must be thrown in, and then trod down, before the lime and water are put in ; the loam will prevent the lime from corroding the metal.

wards and forwards, that no part of the tree be missed. This should be done in cloudy weather, or when the sun is off the wall. If the trees are on an East wall, you may begin to water them about half-past eleven o'clock; if on a North wall, you may water them the first thing you do in the morning; and if on a South wall, at four o'clock in the afternoon; repeating the watering for at least six days successively. But if there be cold Northerly and Easterly winds, or frosty nights, the watering should be discontinued till the weather is milder.

Be always careful that your trees get dry before night, and be sure never to water when the sun is on them, nor yet water them with the grounds of the lime, which will make the trees look very unsightly, and also injure the leaves.

When aphides are numerous at the ends of the shoots, the leaves there will be curled up; these should be stript off, and the insects crushed with the foot.

#### *Of the Acarus.*

The Acarus, or Red Spider, is one of the most destructive insects that can infest plants, particularly in forcing-houses.

These insects have no wings, and the female is oviparous.

There are not less than 82 species of this genus. The Acarus is very common on trees, particularly

the Currant, on the fruit of which it is frequently seen running.

These insects attack the Vines, Nectarines, Peaches, and Cherries : and forced French-Beans are very subject to their depredations, as are also Peaches and Nectarines on the natural wall, in hot weather. Melons in frames are very much infested with them. I once saw a ridge of Melons, of seventy lights, so much injured by them, that when the fruit was full-grown, it was good for nothing, and the stems and leaves were completely exhausted of their moisture by these insects feeding on them. They are equally hurtful to most exotics in hot-houses.

The best thing that I know for destroying these pernicious insects is moisture ; which will also destroy many other insects in hot houses.

Frequent watering of wall-trees, standards, &c. with lime-water (the making and using of which is described in the directions for destroying the Aphis), and throwing it plentifully on the under-side of the leaves, where the *Acarus* is generally found, will in a short time extirpate that destructive insect.

For plants, &c. in hot-houses, I would recommend using water only, and in the following manner :

Between three and four o'clock in the afternoon fill the barrow-engine with soft-water, or such as has been exposed to the sun all day, and wheel it along the foot-paths of the house, where they are

wide enough to admit it, and sprinkle all the plants, pressing your finger on the top of the pipe, to spread the water like a fine shower of rain, playing also against the top lights and shelves till the water stands an inch deep in the paths of the house.\* If you cannot conveniently get the engine into the house, open the front lights, or when there are no front lights, slide down the top lights, and throw the water in at the front or top. When you begin this operation, if in the inside, every light must be shut; and if you throw the water in at the front, you must keep only one light open, which shut immediately when you have sufficiently watered that part of the house opposite to it: and, then opening another light, proceed as before; and so on, till the whole is properly watered. The house must then be kept close shut till next morning: this will cause such an exhalation from the glass, tan, (if there are any tan-beds in the house,) &c. that the plants will be covered all over with the vapour, which will infallibly destroy the Cocci, Aphides, and other insects: but the watering must be repeated every afternoon, during hot weather only. By this you will also save a great deal of labour in watering; but such plants as require much watering should be watered before you begin to sprinkle the house. Before morning the

\* I have lately seen a small copper engine, made by Mr, Phillips, Engine-maker, Blackfriars Road, which answers very well, when a barrow-engine cannot be got into the house.

plants will have imbibed all the moisture, and the paths will be perfectly dry.

When I lived at the Botanic Gardens, Chelsea, I observed in hard Winters, when we were obliged to keep strong fires in the stoves night and day, that the plants which stood on shelves in the dry stoves were so scorched up that the leaves used to drop off, as from deciduous trees in Autumn, which gave them a very disagreeable appearance. This induced me to consider what could be done to prevent it; when the following method occurred to me: about eight in the morning, when the sun shone out, and there was the appearance of a fine day, I threw in water till it covered the floor, which was of tile, from one to two inches deep, and kept the house shut the whole of the day, unless the thermometer rose to about eighty degrees, which seldom happens at that season of the year; in that case I opened the door to admit a little air. By the middle of the day the water was entirely exhaled, and the floor perfectly dry. This I used to repeat two or three times a week, in sunny weather: the plants in about a week's time began to throw out their foliage, and in a fortnight or three weeks they were in full leaf. This success induced me to take the same method with the tan-stoves and other houses in Summer, when troubled with insects, and I had the satisfaction to find that it had the desired effect.

*Of the Acarus on Melons.*

As we are now treating of insects, although it may look like a departure from my original plan, I hope that some instructions for destroying the Red Spider on Melons will not be unacceptable.

Melons, in dry weather, and with a dry heat, are very apt to be infested with the red spider; and you may always observe the symptoms long before you can see these insects with the naked eye, by the leaves curling and cracking in the middle. Whenever you observe them in that state, in fine warm sunny weather, I would recommend watering them all over the leaves from a watering pot with a rose, or an engine, about six in the morning; and about eight o'clock shade them with mats, if the sun shines, and shut the frames close down till about eleven; then admit a small quantity of air, letting the mats remain till about three in the afternoon, when they should be taken off. Shading with mats will prevent the leaves from being scorched by the sun while they are wet. If the Wind be South or South-West, I should recommend watering them again about three in the afternoon, shutting them up close to keep the heat in, which will cause a strong exhalation, and destroy the spiders, as they by no means love moisture. In watering, throw as much as possible on the underside of the leaves, where the insect generally lodges; the Vines may be gently turned, tak-

ing very great care not to hurt them ; by which means you can easily throw the water all over the underside of the leaf ; which must be done in a gentle shower from the engine, or from a watering pot with a rose, so as not to wash up the mould on the plants : at the same time throw great plenty of water on the lights and sides of the boxes. After you have done watering, lay the Vines gently down again in their former position. If a sunny day, let the mats remain as before directed until the leaves of the plants are perfectly dry, admitting air according to the heat of the day.

Before the frames and lights are used, I would recommend washing them well, both inside and out ; first, with clean water, and then with soap-suds and urine mixed ; using a brush or woollen rag in the washing ; this will kill the eggs of the spiders and other insects that may have been deposited the preceding season.

When the ridges are fit for putting the mould on for the hills to plant the Melons in, it should be from a foot to fifteen inches deep, and the rest of the bed should be covered with light mould, or rotten leaves, about one inch deep to keep down the steam. Take care not to make the hills too broad at first (a wheelbarrow full and a half will be enough for one hill), and observe that the heat is not too great, which will burn the mould and the roots of the plants. You will know, when the beds are of a fine temperate heat, from sticks stuck

in at different parts of the bed, by the feel of your hand, and the sticks having a pleasant sweet smell.

It will be very proper to water the hills, with a watering pot having a rose, once a day for two or three days before you put in the plants, keeping the lights shut, which will destroy any eggs of the spider that may yet remain in the crevices of the boxes and lights.

The day on which you mean to put in the plants, you should give the beds a great deal of air, to let out the steam that has been penned in; then turn over the hills, and put in your plants about three o'clock in the afternoon, making a hollow circle round the bottom of each hill to separate the mould of the hills from that on the bed, which will suffer the steam to evaporate more easily; then watering the plants, shut them down till next morning, admitting air according to the heat of your bed, taking care not to give too much till your plants are well rooted in the hills, which will be in a couple of days; it will also be necessary to shade them in the heat of the day, to prevent the plants from flagging.

In cold frosty weather you must by no means sprinkle the plants, as the frost in the night will infallibly bring on the canker.

Soft water should be used in sprinkling, or such as has been exposed several days to the sun. If the water be very hard, put some wood-ashes into it, and stir it up two or three times a-day:

it will be fit for use in the course of two days; let the ashes subside, and use the clear water only.

If your Melons have been infested with the spider in the preceding year, by no means use any of the mould again.

*Of the Coccus.*

The Coccus is a genus of insects belonging to the order Hemiptera, whose males have wings, but the females have none.

The most common insects of this genus are those which attach themselves to Peach, Nectarine, and Pear trees; and when full grown they have somewhat the appearance of a boat with the keel turned uppermost. These are apparently without feet, eyes, or other members, while in this state; and so much resemble some kinds of galls, or excrescences of the bark, as frequently to be taken for such. A thin film of a white cotton-like substance is interposed between the flat part of the body and the tree. This is commonly, in a greater or lesser quantity, to all the species, and appears at first all round the edge as a kind of cement, to join it to the tree.

The males are very few in proportion to the females, and not nearly one-fourth of their size; they are beautiful little flies, which, after a short but active life, terminate their existence without having tasted food, being provided with no sort of organs for that purpose.

Peach, Nectarine, and Pear-trees, are very much infested with these insects: they frequently cut through the bark, and the trees then appear as if they had been scratched by cats. I have seen some trees with this appearance all over them.

When these insects first appear on the bark, they should be scraped off with a wooden knife, and the stem and branches of the tree well washed with soap-suds and urine, applied with a stiff painter's brush. This should be done in February, before the buds begin to come out. But if the outer bark is perforated, it must be cut or pared off with a long knife; and if you find any brown spots in the inner bark, they must be carefully cut out. This disease is one great cause of the canker, and of the death of the tree. [See PLATE IX. *Fig. 3.*]

When this disease has made its way through both barks, as is often the case, the branches on each side of the tree may be cut close to the stem, if it has an upright one; but if the tree be trained fan-fashion, the best way is to head it near to the place where it was grafted. I have headed old Pear-trees which were so dead except a small strip of live bark on one side, that you might rub the bark off them as easily as off a bundle of faggot-sticks that had been cut upwards of a-year; yet these trees have shot out fresh branches to the length of seventeen feet in two years, and produced fine fruit the second year. Apply the Composition

immediately after heading, or cutting, or paring off the diseased bark.

A very destructive species of the Coccus tribe (*Aphislanigera* of Illiger), has lately done incredible damage to the Apple trees in the nurseries and gardens in the neighbourhood of London. Some Nurserymen have lost several thousand Apple trees in one year. These insects attach themselves to the bark by their suckers, and, by feeding on the juices of the tree, rob it of its nourishment. Such trees as are infested with them have a sickly appearance. I am happy, however, in being able to say, that I have nearly extirpated them from His Majesty's gardens at Kensington: but, as our neighbours do not pay the same attention to their trees as we do to ours, the insects frequently emigrate to us; this obliges me to be very attentive to their first appearance; and, as I take the earliest opportunity of destroying them, the trees suffer very little from their depredations.

These insects make their nests generally where branches have been cut off, or in hollow places, where the canker has eaten holes in the trees. Their first appearance is like a white down; on touching, or rubbing them, they tinge the fingers of a crimson colour, like cochineal. If suffered to remain long on trees, they take wing, like Aphides. The method that I have followed for these ten years to destroy them is as follows:

I rub the places where their nests are with an

old brush, such as painters use, till they are all cleaned off; and if the part be canker-eaten, I cut it clean out with a knife or chisel: I then take of soap-suds and urine equal parts, and with this I wash the wound and the bark all round it; and with a brush apply the Composition mixed with wood-ashes and the powder of burnt bones, covering the wound all over with it. Afterwards I shake some of the powder of wood-ashes and burnt bones, mixed with an eighth part of unslaked lime finely powdered and sifted, over the hollows, or where knobs have been cut off.

At the same time that the trees are cleared of the Cocci, the Caterpillars should be picked off.

The first time that I observed the new Coccus, which has done so much mischief to the Apple-trees about London, was in a garden of my own at Chelsea, about the year 1782 or 3; and, as far as I can learn, they were imported, among some Apple-trees, by the late Mr. Swinton, of Sloane-street. Mr. Swinton afterwards removed his nursery to the King's road, near Chelsea College, which now goes by the name of the Foreign Nursery.

All the gardens about Chelsea and Kensington are now very much infested with these insects; and I have frequently seen them in several other parts of the kingdom.

Doctor George Fordyce purchased several Apple-trees at the sale of the effects of Mr. De la Tour, Editor of the *Courier de l'Europe*; all of which were from Mr. Swinton's nursery, and all infected

with these insects. The Doctor gave me twelve of these trees, which I planted, and very soon cleared them of the Coccus.

Messrs. Lee and Kennedy, Nurserymen at the Vineyard, Hammersmith, Messrs. Grimwood and Co. Kensington, and Messrs. Gray and Wear, at Brompton-Park Nursery, have applied train-oil, laid on with a painter's brush, with a view of destroying these insects, but they have not been successful. \* Indeed, I by no means approve of applying oil to trees upon any account, as by shutting up the pores, it is apt to render them bark-bound.

See *Nat. Soc. Trans.* VOL. II. p. 162.

#### *Of Caterpillars.*

Caterpillars are very destructive to Cabbages, and all the Brassica tribe, and frequently make depredations on trees, particularly the Apricot. They should, therefore be carefully observed and picked off. A few years ago, Kensington gardens

\* Since writing the above I have been informed, that the farmers in Kent likewise use train-oil; but if they would make a fair trial of urine and soap-suds, they would find it more effectual, and it would cost nothing but labour: besides, what falls on the borders will make a fine manure. The urine and soap-suds should be saved in tubs in Winter; and, as it will be too strong for use in Summer, it may be lowered by adding water. This mixture will also be found effectual in killing slugs that harbour about the roots of the trees and bottoms of the walls. When it soaks into the ground, the slugs will work their way out, and may easily be killed by throwing a little more of the mixture on them from a watering-pot with a rose.

were very much infested with them; but by carefully picking and destroying them, and all the aurelia that can be come at, very few are now to be seen. During the Winter and Spring, every chrysalis that can be found under the copings of walls, on gates, palings, &c. should be destroyed. Many may also be found about the doors and windows of houses, under the eaves, and in many other places.

The best method of preventing trees from being infested is, to scrape the stems with a piece of bone or wood made in the form of a knife, taking care not to bruise the bark; and afterwards to wash the tree and wall with an equal quantity of soap-suds and urine mixed.

As soon as the leaves are off the trees in Autumn, they should be raked and swept up; then carried to the Melon-ground and mixed up with other leaves and dung for hot-beds: by this means you will get rid of a great number of eggs of insects that are deposited on the underside of the leaves. Then wash all the stems of the trees, and all the ends of the buds, taking care not to hurt the buds: in doing this, what falls will destroy the slugs that take shelter on the offset of the wall and in the borders, before they are dug for planting lettuce, endive, &c. This washing should be repeated about the beginning of February, which will destroy any eggs of different insects that may still remain about the trees. A painter's brush may be used for laying the mixture

on the trees, and a soft broom, or a brush made of the ends of garden matting, for washing the wall. The matting seems preferable, as being soft and flexible, it will enter the holes and crevices.

The mixture that falls on the border and offset of the wall, in this second washing, will destroy those slugs and insects that made their appearance early. The stems and branches of the trees may be washed two or three times, or oftener, in the Spring, before the buds begin to swell; but the branches must not be rubbed after the trees come into flower; you may, however, sprinkle them over with the mixture from a watering-pot with a rose just before the buds begin to open, but by no means after they are open; as it will, by its glutinous nature, render the bloom liable to be scorched by the sun.

I would recommend the above washing, &c. for all trees, standards as well as those on walls; particularly Apple, Cherry, and Plum trees.

If any Caterpillars should remain, they will be discovered by the curling of the leaves; for every curled leaf has one or more caterpillars, or other insects, in it; they should therefore be carefully pulled off, and the insects crushed: if neglected, they will frequently devour every leaf, leaving the tree quite naked, and of course destroy the fruit for that season.

There are some gregarious sorts of caterpillars found in great numbers enclosed in a net, or bag, resembling a strong cobweb, and fixed to the

branches of trees and shrubs. These nests should be carefully picked off, and the insects crushed, by which vast numbers of them will be destroyed. After you have cleared the tree as well as you possibly can, wash it as above directed, which will destroy those stragglers that may still remain on it.

Observe, that after the trees come into flower, instead of washing them with urine and soap-suds, they should be well watered with clear lime-water, mixed with tobacco-water.

There are several species of moths that in the caterpillar state are very hurtful to Plums and other fruit-trees: it will, therefore, be a great advantage to destroy them on their first appearance.

It would be of great service to get acquainted as much as possible with the economy and natural history of all these insects, as we might thereby be enabled to find out the most certain method of destroying them. Were a few of each sort of caterpillars put in a box or case, and fed with leaves of such trees as they generally live upon, they might be observed from time to time until they come to the chrysalis, and from that to the moth or butterfly state, and thus a more perfect knowledge of them might be obtained.

It would be necessary to have separate divisions in the case for each different species, and to put some earth in the bottom of each division, which should be moistened occasionally, as some of them

bury themselves in their chrysalis state, while others adhere to walls, gates, or palings.

Fresh leaves should frequently be put in, and the box or case covered with a piece of fine canvass, or gauze, to admit the fresh air.

At the same time that the trees are cleared of the Coccus, Aphis, or any other insects, the Caterpillars should be carefully looked for and picked off. You will observe, that they shelter themselves at the end of the shoots, in the flowers, and at the bottom of the footstalks of the flowers. There are two or three sorts that infest fruit-trees, two of a brown and one of a green colour. Four years ago the Apple-trees suffered very much by a blight; they had all the leaves eaten off, and, of course, bore no fruit. I first had all the Caterpillars carefully picked off: I then cut out the cankered wood, and washed the trees with a mixture of urine, soap-suds, and fresh cow-dung, sufficient to bring it to the consistence of paint, laying it on all over the stems and branches of the trees, particularly where the decayed parts were cut out: after this, the trees recovered in a manner that surprised every one who saw them: and they still continue in a thriving state, and bear very fine fruit.

In 1795 I used the above method with a great many dwarf Apple-trees; and the effect was so visible next season, that all who saw them took notice of the great difference between them and the remaining trees, which we had left to nature;

the latter bearing no fruit, and their leaves being eaten by the caterpillar, while the former have borne fine clean fruit ever since.

The trees, twenty-five in number, which I left to nature, continued in a sickly state for three years, neither bearing fruit nor putting forth shoots. After the third year I headed them down, scraping the stems and clearing off the insects; they are now recovered, having made as fine wood as the others, and are in a healthy flourishing state.

*Fig. 2. PLATE IX.* represents different states of a kind of moth, whose caterpillar has for many years done great mischief among Pear-trees on walls. One wall in particular, in Kensington gardens, was very much hurt every year, for several years successively. I imagined that it had been the effect of lightning, or a blight; till, on picking off the Caterpillars, we found a small sort in its case, sticking to the leaves, as at *a*. (*See the description of the PLATE.*) All the first leaves were destroyed by the Caterpillars: I was, therefore, rejoiced that I had found out the cause of their being so much injured every year, being perforated in many places, and dropping off very early.

#### *The Chermes.*

Chermes is a genus of insects belonging to the order Hemiptera, and of which there are twenty-

six species. They take their specific names from the different plants which they frequent; as the *Chermes graminis*, or grass bug; the *Chermes ficus*, or fig-tree bug, &c. The latter is one of the largest of the genus, and is brown above and greenish beneath. It has four long wings, which are placed in form of an acute roof. The larva, which is of an oblong form, has six feet, and its motion is slow. When it is attempted to catch the *Chermes*, it makes its escape rather by leaping than flying, by means of its hinder legs, which play like springs. Some of these insects have a manoeuvre worthy of notice. Several species are provided at the extremity of their body with a small sharp-pointed implement, but which lies concealed; and this they draw out in order to deposit their eggs, by making a puncture in the plant that suits them. By this method, the fir-tree *Chermes* produces that enormous scaly protuberance which is to be found at the summit of the branches of that tree, and which is formed by the extravasation of the juices occasioned by the punctures. The young larvæ shelter themselves in cells contained in the tumour. The directions for destroying the *Coccus* are applicable to this insect.

#### *The Thrips.*

The Thrips, of which there are eleven species, also belongs to the order Hemiptera. This insect

is, in general, so small as to be scarcely discerned by the naked eye. It is, however, very pernicious to fruit-trees, sometimes attacking the fruit as well as the leaves. To destroy this insect, follow the directions given for destroying the Coccus.

*The Phalæna, or Moth.*

There are numerous species of this well-known insect, and their caterpillars differ greatly as to size, shape, and colour. All of them, after casting their slough several times, spin their cocoon, in which they are transformed to chrysalids. They are frequently found in this state, rolled up in the leaves of fruit-trees, particularly those of Pears, Plums, and Cherries. These leaves must be carefully picked off, and the insects crushed: the trees must then be washed with clear lime-water, mixed with tobacco-water. This washing would be found useful when the insect is in its larva state, after picking off and crushing as many of the caterpillars as possible. See CATERPILLARS. (*Page 388.*)

*Sphinx, or Hawk-moth.*

There are one hundred and sixty-five species of this genus, ten of which are found in Great Britain and Ireland.

The name of Sphinx is given to this genus on account of the singular attitudes of their cater-

pillars, who apply the hinder part of their bodies to a branch of a tree, and hold the rest of it erect like the fabulous Sphinx. Most of them spin their cod under ground. The Sphinges appear either early in the morning, or after sunset, and fly heavily and sluggishly, often emitting a kind of sound. Many of the caterpillars are green and smooth, some brown or yellow, and others are spotted, or have belts. The Sphinx may be destroyed by the same method as the *Phalæna*.

*The Phalæna Bombyx Neustria.*

The *Phalæna Neustria*, or Lacquey Moth, lays its eggs in rings round the branches of fruit-trees, exhibiting the appearance of a necklace. These being very hard, and adhering close to the bark, must be cut off with a sharp knife, taking care to wound the bark as little as possible; and wherever the knife enters, it will be necessary to rub in a little of the Composition.

*The Papilio.*

The *Papilio*, or Butterfly, belongs to the order *Lepidoptera*. There are a great many species of this genus, generally distinguished by the colour of their wings. The more common sorts, with their caterpillars, are so well known as to render a description of them unnecessary. The caterpillars

and chrysalids must be carefully picked off, and the trees well watered with clear lime-water and tobacco-water mixed.

*The Cicada.*

The Cicada, Frog-hopper, or Flea Locust, is a genus of insects belonging to the order Hemiptera. The larvæ of several of this genus evacuate great quantities of a frothy matter upon the branches and leaves of plants of trees, in the midst of which they constantly reside, probably for shelter against other animals; perhaps, also, the moisture of this foam may serve to secure them from the sultry rays of the sun.

As the froth emitted by these insects is very unsightly, and as they are also hurtful to trees, by eating the leaves, they should be destroyed by rubbing off the larvæ with the hand, and afterwards watering the tree plentifully with soft water.

*Of Earwigs. (Forficula Auricularia.)*

Earwigs are very destructive to fruit, particularly Peaches. The method that I would recommend for destroying them, and which I have long pursued with success, is as follows:

Take old bean-stalks, cut them about nine inches long, tie them up in small bundles with some packthread, or with small yellow willows, and hang them on nails against the wall, at

different parts of the trees. The first thing you do in the morning, being provided with a board about eighteen inches square, and a small wooden trowel, take down the bundles of bean-stalks, one by one, strike them against the board, and with your trowel kill the earwigs as they fall out of the stalks. If you follow this up every morning (or every other morning,) you will be able to keep them under.

The foregoing method will answer for any sort of trees infested with earwigs. In some years I have seen a great part of the fruit, especially the smooth-skinned sorts, destroyed by these insects and a small green caterpillar; and in a scarce year of fruit, the leaves of Peaches are frequently destroyed by them.

The shreds taken from trees that have been unnailed in Autumn, should be soaked in boiling-hot soap-suds for three or four days, previous to their being used again; this will kill the eggs of earwigs and other insects that may be deposited on them.

#### *Of the Ant. (Formica.)*

The Ant is very destructive to fruit, especially the Peach when ripe. You will frequently see these insects travelling all over the trees, and sometimes the fruit will be filled with them. The best method that I have found to destroy them is, to get a sharp-pointed wooden-stake, or an iron crow,

if the ground be hard, and with it bore a hole close to the side of the wall, and as deep as the ground will permit. By stirring the earth you will set the Ants in motion; then work your stake or crow round the sides of the hole, making them as smooth as you can: the Ants will come to the mouth of the hole, and tumble in, and, by the shape of the hole and smoothness of its sides, will be prevented from climbing up again. When you see a great many in the bottom of the hole pour in some water from a watering-pot; and thus you may drown thousands of them. It is to be observed, that there must be several holes made, according to the length of the wall.

This is an easy and simple way to get rid of Ants. Some are of opinion that they do good, by eating the Aphides from off the trees; but I have always thought that they do much more hurt than good.

You may likewise destroy many of them by mixing quick-lime with soot, and laying it along their roads where you see them thickest; but where you can come at their nests, the best way is to put a piece of quick-lime into it, and pour as much water over the lime as will slake it, the heat of which will destroy them: when you have poured in the water, cover the lime with a turf or a little earth, which will render it more effectual, by confining the heat. You may slake the lime with a mixture of urine and soap-suds, which will render it still more effectual.

If a little of the powder of stavesacre be laid on the ground round the stem of a tree, it will prevent Ants from ascending it.

*Slugs. (Limax.)*

These insects are frequently found harbouring about the foundations of walls, and about the roots of Pease, Lettuce, &c. They may be picked off and killed, by putting them into a pot in which is a little fine unslaked lime; or the ground where they are should be well watered with soap-suds and urine, mixed with tobacco-water. When they are numerous on the surface of the ground, which frequently happens after rain, or in a dewy morning, fine unslaked lime thrown over the borders, &c. will destroy them. But I prefer the above mixture, which, if the ground be well watered with it, will bring them up out of their holes, when they very soon die: it will also destroy their eggs, which they always deposit in the earth.

*Snails. (Helix.)*

Snails, during the Winter, gather themselves together in clusters: and in that season are frequently found in great numbers behind wall-trees and in holes of the walls. They must be carefully picked off and crushed, which is the only effectual way of getting rid of them. If any should escape, they should be destroyed as they make their

appearance in the Spring. As they also deposit their eggs in the ground, the borders should be well watered, as directed for Slugs.

*Of Wasps and Flies.*

As soon as the wasp and large flesh fly (which are very destructive to all kinds of fruit, particularly Grapes) make their appearance, get ready several bottles or phials; then mix up grounds of wine, or beer, with sweepings of sugar, honey, or grounds of treacle, and with this mixture fill the bottles half or three quarters full, then place some of them at the bottom of the wall, and hang a sufficient number up by a piece of yellow willow, or packthread, on the nails against the walls in different places, observing to empty them frequently, as they fill with flies and wasps; first pour the liquor into an empty bottle, and then shake out the dead insects, crushing them with your foot, that none of them may revive: then pour back the liquor into the bottles and phials as at first. In this manner you may destroy a great many before the fruit becomes ripe. If you begin to hang up the bottles as soon as you see the fly, which comes much earlier than the wasp, you will be able to destroy great numbers of them, and will have the bottles ready for the wasps when they make their appearance. The fly will be found as destructive as the wasp to Grapes.

When the weather is hot, and the wasps are nu-

merous, if they do not enter the bottles fast enough (which will happen when the fruit is very ripe), take a little oil in a cup, and with a feather dipped in it touch their backs, and they will instantly drop down; on observing, you will find them turned black and green by the effects of the oil.\* It is amazing what numbers a diligent person can destroy in this way in a day. Oil has the same effect on flies; but it is very difficult to touch them with it as they are so quick in their motions.

#### *Of Birds.*

When fruit begins to ripen, Birds will attack it. The best preventive in this case is, to cover the trees with nets, or buntine, a sort of cloth of which ships' colours are made. These will admit a free circulation of air to the fruit, and will soon dry after rain: they will also be a good covering for the trees in Spring, in cold, wet, or snowy weather.

#### *Rats and Mice.*

These vermin do a great deal of mischief in gardens, in sheds, and other places, where they frequently destroy great quantities of Beans, Pease, and other seeds: it is, therefore, the interest of every gardener to kill as many of them as possible.

There are different ways of destroying them, by traps and by poison; but I would advise never to

\* Oils kill insects by closing up the lateral pores by which they breathe.

use arsenic, or corrosive sublimate, for that purpose, except under particular circumstances, as they are deadly poison: nux vomica will generally answer the end as well, without the danger. In case of being accidentally tasted by children or others, it will be attended with no worse consequence than leaving a disagreeable bitter taste in the mouth; unless, indeed, a considerable quantity of it be taken, which would, no doubt, prove fatal. \* As it is possessed of a strong narcotic quality, and is found a certain poison for dogs and cats, as well as for rats and mice, all domestic animals should, therefore, be kept from the places where the poison is laid. A very good way to prevent accidents is, to enclose the traps in cases, having holes in the ends of them large enough to admit the rats, but small enough to exclude dogs, cats, &c.

*A Bait for Rat-Traps.*

Take a pound of good flour, three ounces of treacle, and six drops of the oil of carraways; put them all in a dish, and rub them well together till they are properly mixed; then add a pound of crumb of bread.

Set the traps, baited with some of the foregoing mixture, as near their haunts as possible; but, for two or three days, so as not to fall or strike on the rats going in, and let them have free liberty to go

\* It has been taken in doses of from five to ten grains, twice a day in intermittents and dysenteries.

in and out at pleasure ; this will make them fearless. Lay some of the bait at the rat-holes, and scatter a little of it quite up to the traps, and so on to the bridge of each trap, where you may lay a handful. It may also be proper to scent the traps with the following mixture, for the purpose of enticing the rats into them.

Take twenty drops of oil of rhodium, six or seven grains of musk, and half an ounce of oil of anniseed ; put them in a small phial, and shake it well before using : — then dip a bit of twisted paper, or rag, in the mixture, and rub each end of the trap with it, if a box-trap, and put two or three drops on the bridge, leaving the paper or rag in the trap. Of whatever kind the trap is, it should be scented : once in a twelvemonth will be sufficient. Then throw some chaff, mixed with a little wheat, about the bottom of the trap, in order to deceive the rats ; for they are very sagacious, and will not enter a suspicious place. This will be necessary to be done only at the first time of setting the traps ; for after some rats have been caught and have watered and dunged in them, rats will enter boldly when they find others have been there before them ; do not, therefore, wash or clean out the trap, as some people do before they set it again ; but let the dung and urine remain in it. Keep the places where the traps are set as private as possible ; and when you set them for catching, mix no bread with the bait, as the rats will in that case be apt to carry it away.

When you find the holes quiet, and that no rats use them, stop them up with the following composition. Take a pint of common tar, half an ounce of pearl-ashes, an ounce of oil of vitriol, and a good handful of common salt, mix them all well together, in an old pan or pot. Take some pieces of paper, and lay some of the above mixture very thick on them, then stop the holes well up with them, and build up the mouth of the holes with brick, or stone, and mortar: if this be properly done, rats will no more approach these, while either smell or taste remains in the composition.

*To kill Rats in Places where you cannot set Traps.*

Take a quart of the bait already described, then rasp into it three nuts of nux vomica, and add a quarter of a pound of crumb of bread, if there was none before; mix them all well together, and lay it into the mouth of their holes, and in different places where they frequent; but first give them of the bait without the nux vomica for three or four succeeding nights; and when they find it agrees with them, they will eat that mixed with the nut with greediness.

Rats are frequently very troublesome in sewers and drains. In such cases, arsenic may be used with success, as follows: take some dead rats, and having put some white arsenic, finely powdered, into an old pepper-box, shake a quantity of it on the foreparts of the dead rats, and put them down

the holes, or avenues by the sides of the sewers at which they come in; this puts a stop to the live ones coming any farther; for when they perceive the arsenic they will retire immediately; whereas if you were to put down the dead rats without the arsenic the live ones would eat them.

What has been said relates chiefly to rats; we shall now give some directions for destroying mice.

Take a quart of the bait prescribed for rats before there is any bread mixed with it; then take four nuts of *nux vomica*, and rasp them very fine, otherwise the mice will pick out the food from it, on account of its bitter taste: rub them well together; lay some of it on a piece of paper, or, if without doors, on a piece of tile, removing all other food from the place, and it will kill all that eat of it. What is not eaten, take away in the morning, and replace it at night. If this be in a garden, shelter it with boards, or tiles, that it may not get wet.

I would recommend setting fourth-figure traps in gardens; these are so well known to gardeners, that they need no description. They may be baited with garden beans.

Traps are also made by stringing garden beans on a piece of fine pack-thread, as you would string beads, then driving in two small stakes at the breadth of a brick from each other, and setting up a brick, or stone, or a board with a weight on it, inclining to an angle of about forty-five degrees; then tie the string with the beans on it, round the

brick and stakes, to support the brick in its inclining position, taking care to place all the beans on the under side of the brick. The mice in eating the beans will also cut the packthread, and so disengage the brick, or stone, which, falling on them, kills them.

There is nothing new in the foregoing method; but as field mice will seldom enter a close trap, I thought proper to mention it.

As mice are frequently carried into gardens with straw, or litter, and are there extremely hurtful, destroying Beans and Peas in Spring, as also Lettuces, Melons, and Cucumbers in frames, it is necessary to take some pains to destroy them.

## INTRODUCTION.

It redounds very much to the general honour of the British nation, as well as to the particular credit of the Society for the Encouragement of Arts, Manufactures, and Commerce, and several other associations for the advancement of Agriculture, &c. that the face of the country has, in the course of the present century, received so much improvement, and such added beauty.

The premiums and honorary marks of distinction held forth by these societies have excited a spirit of emulation, or suggested a spirit of improvement, among persons of every rank of life, which have been productive of many discoveries of no common benefit in their present effects, and of great promise from their future consequences, to the community at large.

But notwithstanding the strides which modern

agriculture has made towards perfection in many points, there is one particular and very interesting branch of this science which improvement has not yet embraced, viz. the growth of timber, and the culture and management of plantations, both of fruit and forest trees.

The profession of a gardener has been the employment of my life; and during a long succession of years, it has been an object of my particular study to investigate and discover the latent causes of those various defects and diseases to which all kinds of trees are more or less subject, and the injuries resulting from them, by obstructing the fertility of fruit trees, and diminishing the quantity, as well as quality, of timber in forest-trees.

Having acquired a competent knowledge of the evil in all its appearances and effects, my attention was directed toward the discovery of such a remedy as might not only counteract the progress of these diseases in fruit and forest-trees, but also afford nature such powerful assistance, that she might be enabled to renovate, as it were, fertility in the one, and sound timber in the other. Of my success in these endeavours to promote the general advantage of this country, in a matter so connected with its best interests, I have that clear conviction which, I trust, will be hereafter communicated to every part of the kingdom where the application of my experience shall be made and prosecuted.

The inquisitive spirit which accompanied my professional pursuits, with the natural desire of improving my private practice in the management of the various kinds of trees under my care, led me by degrees to this discovery. The idea, however, of making it public never occurred to me, till the many trials, and experiments that I had repeatedly made, both on fruit and forest-trees, in the Royal gardens at Kensington, had attracted the notice of many persons of high rank, as well as philosophical eminence, and prompted them to favour it with a particular examination. Their investigation of my process and method of curing the defects and injuries which, from various causes, those trees had sustained, by producing conviction in their minds, gave the most flattering encouragement to me. Indeed, the application of the remedy had been attended with such uninterrupted success, that its salutary and certain effects were evident to every one who favoured it with an attentive observation. Many who visited me, with the most decided opinions against the successful application of any remedy for trees in a very advanced state of decay, did not hesitate, on an investigation of the subject, to acknowledge that their prejudices were not only removed, but that their judgments were perfectly convinced of the powerful efficacy of the discovery, and the very great advantages which, both in an individual and a national view, might be derived from it.

Among the more early enquirers, were the Commissioners appointed by Parliament to examine into the state of the woods, forests, and land revenues of the crown; who, in the course of their surveys, had perceived a great number of trees in the Royal forests to be materially injured; and their anxiety to prevent the loss, or farther damage, of so much valuable timber, induced them to honour me with a letter \* concerning the effects of injuries done to oak-trees, and the means of preventing or curing defects in timber from various causes therein stated.

In reply to this inquiry of the Commissioners, I did myself the honour of addressing them two successive letters. †

Shortly after the date of these letters, the Commissioners favoured me with a visit at Kensington, to examine the process and mode of cure which I had adopted, as well as the effects which my remedy had produced on trees of various kinds and ages to which it had been applied. Those gentlemen seemed, in a most particular manner, to interest themselves in ascertaining the utility and benefit that might arise from the application of it to many thousand valuable trees in His Majesty's woods and forests, which had received injuries of such a kind as, if left to the unassisted efforts of nature, would occasion a very considerable diminution in the

\* See No. I. of the Appendix.

† See Nos. II. and III. of the Appendix.

value, and the quality of the timber, and might even terminate in their entire ruin.\*

This very attentive and minute examination of the several objects of their enquiry being followed by the clearest conviction of the great public utility which would result from a general application of the remedy, the Commissioners were pleased to make a representation of it to the Lords of His Majesty's Treasury, under whose sanction it was submitted to the consideration of the House of Commons by Mr. Rose, on the 24th July, 1789: and on his motion, an humble address was presented by that honourable House to His Majesty, on the subject.†

In consequence of this Address, a Committee of Members of both Houses of Parliament undertook, at the instance of the Lords of the

\* Mr. Nichols, of Redbridge, Hants, Purveyor for Portsmouth Dock, informed me, that the average of the damaged timber brought to that place was never less than one-fourth of the total quantity of timber brought in annually; and not unfrequently it amounted to a third. If, however, the trees that have received injuries were prepared, and the Composition applied as directed in this Treatise, the cavities, or wounds, would be filled up with new and sound wood. And if recent wounds, occasioned by lopping, or breaking off branches, were immediately dressed in a proper manner with the Composition, the tree would sustain no injury; as the wounds would be healed and covered over with new and sound bark in a short space of time; so that there would not be found a foot of damaged timber.

† See No. IV. of the Appendix.

Treasury, to investigate the efficacy of my Composition; for which purpose they most attentively examined the state, condition, and progress of cure of the decayed and injured trees in Kensington gardens, to which it had been applied in experiments of various kinds, for upwards of seven preceding years; and, after having, by a very full enquiry, strict investigation, and the most minute attention, satisfied their minds in every particular, they reported to the Lords of the Treasury the result of their examination, expressing their unanimous opinion and conviction, that "The Composition was a discovery which might be rendered highly beneficial both to individuals and the Public." That Report, and also a Letter previously written to the Committee by the Commissioners of the Land Revenue, of which I have been favoured with copies, are, for the farther information of the Public, inserted in the Appendix.\*

Having been thus honoured by the unanimous approbation of persons so respectable for their rank, character, and knowledge, I proceeded to exert myself in making various additional trials and experiments, to enable me to give farther proofs of the efficacy of my Composition, in restoring the powers of vegetation to trees so far decayed as to be of no value as timber, but which from their situation as a skreen, or as composing,

\* See No. V. of the Appendix.

part of a general uniform appearance in the Royal gardens, it became a desirable object to preserve. Nor were my endeavours less successful in this subordinate experiment, than they had been in those which were directed by circumstances of superior interest; for I had the very great satisfaction to find, that, in consequence of my treatment of trees in that state of decay which has just been specified, a few years' growth has filled up unsightly chasms, and restored that uniformity to their local position, which young plants set in their places would not have accomplished in a long course of successive years.

The Report of the Committee having been laid before His Majesty, in consideration of the great utility and advantage which must arise to the country at large from the use of this Composition, His Majesty was most graciously pleased to order a reward to be given to the author, for making known to the public the materials of which it is composed, with the method of preparing it, as well as the mode of its application; and, in order to diffuse the benefits of this discovery throughout the kingdom, an advertisement\* has been inserted in the London Gazette, and in most of the town and country newspapers.

The very great importance to this country of securing a continued succession of good, healthy, and well-growing forest trees, producing sound, unblemished timber, for supplying the various

\* See No. VI. of the Appendix.

wants of the public, must be evident to every man's reflection; nor need it be observed that numberless large trees, in the woods, parks, and forests, of this kingdom, are from various causes, rendered unfit for use, and the timber so much damaged as to occasion a considerable diminution in its value. This evil arises, in some instances, from unskilful management, and in others from external accidents: among which are, the ruinous effects of hurricanes and high winds, when the trees are generally left, in their wounded and disfigured state, to the accelerated operations of inevitable decay. It also not unfrequently happens, that the heirs of large estates, on coming to the possession of them, order great numbers of trees to be promiscuously felled, before they have attained a state of maturity, without paying the least attention to provide a succession of young trees to supply their place; by such inexcusable negligence defeating the ends proposed by the provident care and wisdom of their ancestors, depriving the public of a valuable source of timber, either for domestic purposes or national use, and reducing their country to a dependence on foreign produce for supplying the demands of her fleets and manufactures.

I shall esteem myself most happy, if, in giving this tribute of information to the general stock of public improvement, I should promote an influence that may excite noblemen and gentlemen, and proprietors of land of every denomination through-

out the kingdom, to be actively solicitous in planting and preserving oak timber, the native growth of their country; that Great Britain may never be under the dangerous as well as disagreeable necessity of trusting the safety of her seamen to the inferior texture and less durable quality of foreign growths; while the hardy oaks of England, which for ages past have been considered as affording the best timber in the world for this building, and may have been said to have brought home victory and commerce from every part of the globe, are no longer suffered to diminish, as they have done of late, to the manifest detriment and dishonour of our country.

Such an evil (and it is of no common magnitude) proceeds from the negligence and inattention of the landed men, who from a spirit of patriotic ambition, as well as private interest, should pay a very vigilant attention to the maintaining of a succession of healthy, well-growing timber, for the service of their country, nor any longer suffer the internal resources of the kingdom to fail in furnishing materials for that great national object, the support of the British navy; as well as for the many various demands of domestic utility. By making such a provision for the public wants, they will add to their own immediate wealth, as well as to the fortunes of those who come after them: and, while I express my wishes that such general good designs may be put in universal practice, I may express my belief,

that the discovery which I have made, and which is now divulged to the public \*, will facilitate the means of prosecuting them, to the essential advantage of the British Empire.

*General Observations on the Diseases, Defects, and Injuries, of all Kinds of Fruit and Forest Trees.*

In the course of more than thirty years' practice in cultivating, pruning, and keeping of garden fruit trees, I have observed, that, from natural causes, accidents, and unskilful management, they were subject to injuries of different kinds, which always diminished their fertility, and frequently rendered them wholly unproductive.

All trees that bear stone fruit are liable to emit a gum, which, by producing a canker, proves fatal to the health and vegetation of the trees. Most forest trees are also liable to what is called a bleeding, which proceeds from any injuries that obstruct the circulation of the juices. Of those which suffer from bad management or accidents, some are injured by unskilful pruning, and lopping at improper seasons of the year: and others by the violence of high winds, having boughs or limbs torn from their bodies; which being left in that state, exposed to all the inclemency of hard frosts, are often cracked or rent in the wood; or from heavy and soaking rains, the wounds imbibe so large a quantity of wet and moisture, as, by causing

\* See Nos. VI. and VII. of the Appendix.

a fermentation with the natural juices, brings on disease, and in time destroys the health and vegetation of the tree. These, among other causes, tend to produce decay and barrenness in fruit trees, as well as defects in timber, to the great loss of the public in general, as well as essential injury to the individual proprietor.

To remove these evils, and to prevent the ill consequences arising from the causes already described, I submit to the experience of the public a remedy discovered by myself, which has been applied with never-failing success to all kinds of fruit trees, and has not only prevented further decay, but actually restored vegetation and increased fruitfulness, even in such as were apparently barren and decayed. It has produced also a similar effect on forest trees, by restoring them to soundness of timber and healthful vegetation, and covering, as it were, visible nakedness and increasing decay, with fresh and vigorous foliage.

This remedy is a Composition formerly applied in the manner of a plaster, but now in a liquid state, and laid over the wounded or injured part of the tree with a painter's brush: it is of a soft and healing nature; possesses an absorbent and adhesive quality; and, by resisting the force of washing rains, the contraction of nipping frosts, and the effects of a warm sun or drying wind, excludes the pernicious influence of a changeable atmosphere.

The discovery of it is the result of much re-

flection and study during a long course of years, and of a great variety of experiments, made, at a very considerable expense, to ascertain the efficacious power of the application. Nor shall I hesitate a moment to declare my firm belief, that wherever it shall be properly applied by the proprietors of gardens, orchards, and woods, it will be productive of all the advantage that can be derived from restoring as well as preserving vigour and fertility in all kinds of fruit trees ; as also from preventing decay, and promoting health and sound timber, in every species of forest trees : and how great that advantage may be, it is in the capacity of every one to determine.

*On the Management of Forest-Trees.*

The received opinion and common practice of most professional men has been, to prune or lop their trees, from the month of October, when the juices have been exhausted by the Summer foliage, autumnal fruit, and general nourishment of the body of the trees, until the month of March, when the sap or juices, reinvigorated by nature during the Winter's repose, begin to re-ascend and perform the annual function of clothing it with fresh foliage, blossoms, and fruit. The reason of this practice is, that, the sap being fallen at that season of the year, it has been considered as the most proper period to lop off all superfluous

growths ; and the efforts of nature to heal the wounds thus necessarily given (before the rising of the sap in the following spring) have been judged best for the safety and health of the tree. The danger of performing this service when the juices are in a more vigorous flow, as in the months of May, June, and July, has been dreaded, from a fear of its occasioning a waste of the nutritive juices, discharging themselves through the wound, to the impoverishment and injury, if not the ruin, of the tree.

The pruning of fruit trees and the lopping off large branches from forest trees during the Winter season, has also been frequently attended with great hurt and impediment to their health and vegetation ; the wounds being exposed to all the rigours of an inclement season, and thereby contracting those diseases which contain the principles of decay. Hence it is that such members of forest trees are continually injured in their value for public uses, either by unskilful management or purposed depredation, or by the violence of boisterous winds, when, their limbs and branches being torn off, the trees are left in that unprotected state to imbibe the seeds of decay and rottenness, which will in time pervade their very heart, and render them unfit for any of those valuable purposes for which nature, by their frame and texture, appears to have designed them.

It may also be observed, that where branches

have been cut off from the body of the tree, even at the distance of two or more feet from the trunk, with a view to prevent injury to the timber, even that method has not been found effectual to save the tree from very material detriment; as the remaining stem of the branch so cut away, dying soon after, becomes a ready conduit for conveying pernicious moisture and disease to that part of the tree with which it is connected; and so on, in time, to the whole.

The practice of others, in lopping their trees close to the trunk, and dressing the part smooth and even, has less objections than the former; nevertheless, even according to this method, the tree is liable to injury. The effort of nature to heal the wounds thus given discovers itself by encircling the wound with a kind of callus or lip, which, increasing in size, and swelling out from the annual flow of the juices, forms a hollow or cavity of the central part, where the rain or snow is very apt to lodge; and penetrating between the bark and the wood, dried and cracked by a hard frost or a warm sun, promotes that fermentation with the natural juices, which is the certain source of disease and decay.

Young, healthful, and vigorous trees, when they have been injured by being wantonly cut through the bark, or from other causes, will sometimes recover themselves, and, to all outward appearance, be restored to their original soundness; but when

cut into planks and boards, internal blemishes and faults are discovered in them, which appear to have been occasioned by the early injuries which the tree had received; the texture of the wood not uniting where the wound was originally given; though, from the youthful vigour of nature, the bark has closed, and an external cure been evidently performed.

As a most efficacious remedy to prevent the evils that I have described, with all their destructive consequences, and to restore sound timber where the symptoms of decay are already apparent, I confidently recommend the use of my Composition, which, being applied in a proper manner to the wounded or injured part, will infallibly prevent the bleeding of trees, or the oozing of juices through the wounds of limbs or branches that have been cut off in the middle of Summer, when they are in their highest vigour, and most rapid flow of vegetation; by which means, any wasteful discharge of the juices is prevented, and they are duly confined to their natural operations of giving nourishment, growth, and fertility, to their respective bodies.

By employing the proposed remedy, trees of all kinds, whether in gardens or orchards, in parks or forests, may with greater safety and advantage be pruned or lopped in the Spring, or early in the Summer, than in the Winter season; as the Composition, when properly applied, repels the flow of the juices through the wound, causes a more active

vegetation, and assists nature more powerfully in healing the wound at the time the sap is in full vigour, than when it is on the decline, as in Autumn and Winter.

It is also necessary to remark, that both fruit and forest trees (particularly those which grow in the shade) are very liable to be affected with disorders proceeding from the growth of liver-wort, and various kinds of moss, that adhere to the outer bark of the tree, and frequently gain a considerable thickness, that not only prevents the natural flow of the juices, but causes a stagnation in the circulation, and brings on decay; which, after destroying the outer bark, penetrates, by degrees, deeper into the wood. Where this circumstance is observed, care should be taken to clear the whole bark of the tree from these growths; and where it is infected, to scrape or pare it away. When the body of the tree is thus cleansed from infection, the Composition should be applied, in a liquid state, to the parts so cleansed, to close the pores of the wood; when the tree will soon acquire a fresh bark, with improved health and vegetation. I am confirmed in these opinions by the many experiments and various trials that I have made to ascertain by the most positive proofs, the properties of this Composition, before I ventured to offer it to the public attention. Indeed, every year's experience has increased my conviction of its general utility, when properly applied to the purposes for which it is recommended. To give a more

complete illustration of its virtues, and to place the advantages arising from it in a stronger light, I shall beg leave to state a few of the very numerous experiments that I have made on the forest trees in His Majesty's Gardens at Kensington, where the salutary effects of the Composition are evident to every attentive observer.

The first trials of its efficacy were made on some very large and ancient Elms, many of which were in a most decayed state, having all their upper parts broken, by high winds, from their trunks, which were withal so hollow and decayed, that a small portion alone of the bark remained alive and sound. Of these trees I cut away at first a part only of the rotten stuff from the hollow of the tree, and then applied the plaster to the place where the operation had been performed, by way of an internal coat of the Composition. In a short time, however, the efforts of nature, with a renovated flow of the juices, were clearly discernible in their formation of new wood, uniting with, and swelling, as it were, from the old, till it became a strong support to that part of the tree where the Composition had been applied. I then cut away more of the rotten wood from the inside, applying the plaster in the same manner, with the same good effects, and continued to use the knife in proportion to the acquisition of new wood ; so that, from the tops of these decayed and naked trunks, stems have actually grown of above thirty feet in height, in the

course of six or seven years from the first application of the Composition ; an incontrovertible proof of its good effects in restoring decayed vegetation.

Many other Elm trees, which had received hurts from bruises and other causes, and where disease and decay were already evident, after cutting away all the infected part, and duly applying the plaster, were so completely healed, that the outline of the wound is scarcely discernible on the bark, and the new wood is as perfectly united to the old, as if it had been originally formed with the tree.

Of Oak trees also, which had received very considerable damage from various accidents, as blows, bruises, and cutting of deep letters, the rubbing off of the bark by the ends of rollers, or wheels of carts, and mutilated branches, a perfect cure has been made, and sound timber produced. The acidity, or corrosive quality, of the juice of Oak-trees, when obstructed in their circulation from any of the causes already mentioned, and fermenting with the wet and moisture imbibed by the wounds from the atmosphere, will bring on disease, and promote decay : for notwithstanding the hard texture of the Oak, when once the principles of decay begin to operate, the acrimonious juices feed the disease, and accelerate its progress, as much, perhaps, as in trees of a softer quality and texture ; but when the diseased or injured part is entirely cut away to the fresh sound wood, and the Composition properly laid on, as perfect

a cure has been made as I have already related in the recovery of Elm trees. Indeed, when I reflect that the Oak has been the boast of our early ancestors, and the means, under the blessing of God, of affording protection and safety, as well as accumulating honour and wealth, to the nation, what language can sufficiently deplore that want of public spirit, and that strange inattention to the preservation and increase of this staple tree, which suffers such numbers of stately Oaks to go to decay; in which disgraceful state they remain to upbraid their possessors, as foes to the commerce and naval glory of the kingdom!

Various experiments have also been made on other forest trees, as ash, limes, chesnuts, and sycamores, that had received the several injuries to which they are exposed; as well as many of the resinous kinds, such as the cedar of Lebanon, and others of the pine tribe; in all of which I have experienced a degree of success that exceeded my most sanguine expectations.

As I feel a strong solicitude to render my experiments of the most extensive advantage to the community, and in particular to the proprietors of landed estates throughout the kingdom, I beg leave to recommend to their particular attention, that all forest trees, whether felled with a saw or an axe, may be cut near to the ground; at the same time carefully preserving the stump and roots from any further injury. The surface should then

be made quite smooth, when the Composition may be spread over the whole surface, according to the directions already given. It should, however, be observed, that the Composition, when employed for this particular purpose, should have an equal quantity of the powder of alabaster mixed with the dry powder generally directed to be used after the Composition is laid on, in order to render the surface harder, and of course better able to resist the bad effects of the dripping of trees, of rain, frost and snow: but this addition is by no means necessary in the usual application to the sides of trees.

In consequence of this process, the vigour of the roots will operate so powerfully in the course of the succeeding Spring, that a considerable number of buds and branches will shoot forth round the stump, which, with proper care and attention, may be trained to many valuable purposes, either straight or crooked, for knee-timber or other uses: and by retaining only so many of these shoots as are designed to grow for any particular intention, more than one half will be saved, in point of time, according to the proportions of common growth: for, if a young tree, be planted in a soil equal in quality to the site of the old stump, the shoot growing from the latter will, in eight or ten years, attain to a size which the single plant will hardly acquire in twice that period. There are also many useful purposes of husbandry, as hop-poles, and other poles

used on various occasions for which a number of shoots may be trained from one stump, whose fertile juices will shortly rear a healthy and numerous offspring around it. Very particular attention, however, should be paid to regulate their number, according to the size and vigour of the stump. It would certainly be proper to leave more of them at first than are intended to be reserved for final use, in order to draw up the sap: if too few are left, they will be liable to burst, from the superabundant flow of the juices from the old stock: to prevent which inconvenience, they should be cut away by degrees, always applying the Composition as they are cut, and leaving the finest stem to produce the new tree, which will in time cover the old stump, and leave nothing but a faint kind of cicatrix at the junction of the old and new part of the tree.

It is needless for me to insist on the great advantage which land-proprietors and farmers will derive from this method of managing their woods and coppice-grounds, wherever they may be. In many counties of England, coppice or underwood is an article in very great demand for charcoal, common fuel, or the purposes of particular manufactories, as well as to furnish a variety of articles for husbandry and domestic convenience.

It would be equally unnecessary to enlarge on what must be so evident to the most ordinary understanding, the great national advantage which

may be derived from the use of this Composition, by preserving and increasing the native supplies of our country for the support of that navy which is to protect it. Nor need I urge to the man of taste, and the lover of landscape beauty, what useful help it may afford to the delightful modern art of ornamental horticulture.

## **APPENDIX.**

**F F**

# APPENDIX.

---

## No. I.

*Land Revenue Office, April 17, 1789.*

SIR,

BEING informed that you have discovered a method of curing defects in growing trees of all ages, which may have sustained damage from any cause whatever, we wish to be favoured by you with an answer to the following questions, relative to injuries done to the bark of Oak trees, and the means of preventing defects in the timber arising from that cause ; *viz.*

1. Supposing a piece of bark of five or six inches square to be cut from the side of an Oak tree of any size, from twenty feet to one load or more, so as to lay the wood bare, and that letters or figures were burnt, or stamped with sharp instruments, into solid wood, where the bark was so taken off, and the tree left in that state so long as

it should continue standing; what effect do you think would be produced by such process upon the body of the tree; whether it would continue to grow, and increase in size in the part from which the bark was taken; or whether any, and what detriment would ensure from it to the timber, if no means were used to prevent it; and whether such detriment, if any, would extend further than the limits of the part deprived of its bark?

2. If you should be of opinion that Oak trees would sustain any material detriment, or become in any degree defective, from the cause above stated; do you know any means by which such detriment may be effectually prevented, in trees which have remained in that state from four, five, or six months to a year; so as to restore the bark, and prevent the trees from becoming defective, and unfit for the use of the navy?

3. If you should be able to suggest a complete remedy for such defects, and if the remedy would be effected by means peculiar to yourself, and unknown to others; we wish to know if you would be willing to undertake to apply it, or superintend or direct the application of it by persons properly instructed by yourself, to any number of trees that might require it in any of the royal forests?

4. In case there should be occasion to apply such a remedy to a very considerable number of trees in the state above described, we wish to know, as nearly as possible, what expence the application would be attended with, by the hundred, or thou-

sand, or any given number of trees, including labour, materials, and every incidental expence.

We shall be glad to receive an answer to these inquiries with all convenient speed: and are,

Sir,

Your most obedient Servants,

JOHN CALL,

JOHN FORDYCE.

*Mr. Forsyth.*

No. II.

*To the Honourable the Commissioners of the Land Revenue.*

*Royal Gardens, Kensington, April 24, 1789.*

HONOURED SIRS,

To the letter you have been pleased to honour me with, I beg in general to say, that, from many years' attention to fruit and forest trees, I have observed every wound, bruise, or injury; even the wanton cutting of the initials of a name on the bark of a tree has been attended with mis-

chief, and often brought on the destruction of the tree, especially if old. In particular I beg to say, that if a tree be young, Nature will exert herself to recover from the injury ; but, if the tree be old, it will cease to grow about the injured part, will not increase in size, the wound will daily increase, and in time destroy all the timber of the tree.

In answer to the second question, I beg to say, that Oak trees are equally liable to decay and detriment, as all other trees, though their decay will be proportionably slow, as they are less porous than many other trees of our island ; though I should add, that after Oak trees are so far decayed as to hold water, their decay is as rapid as most other trees. In answer to the question, “ Do you know any means by which such detriment may be effectually prevented ? ” I beg to say, that after many years’ close application, and strictly critical observation, I am fully convinced, that upon the excision of the decayed part, and the application of a Composition, it is possible to heal any wounded tree, and even to restore it to its former health, if there be only an inch or two of bark remaining, to carry on the circulation of the vegetable economy. This is no theory, but is demonstrated by a great variety of experiments on fruit and forest trees in His Majesty’s Gardens at Kensington, now under my care ; and which trees, upon examination, have convinced all those who viewed them, of the practicability of producing the finest, cleanest, and most prolific branches from stumps in a state of

decay: and with confidence I can assert, that I have succeeded so well with His Majesty's fruit trees, that by cutting out the diseased and dead wood, the trees have produced more and finer fruit in two and three years, than a tree newly planted will in thirteen or fourteen years; and this advantageous circumstance is equally visible in the experiments I have made on Elms, where nothing remained but the bark. The Oak, from experience, I find equally as curable as any other tree; the bark may be restored, and the trees rendered as fit for the navy, as though they never had been injured.

In answer to the third question, I say that I am able to "suggest a complete remedy for the defects;" and that remedy I suppose to be known only to myself, as it is not a secret drawn from books, or learned from men, but the effect of close application, and repeated experiments. As to undertaking the application of the remedy, I must request you will have the goodness to permit me to say, that as a servant of His Majesty, I do not think myself at liberty to form any engagement that must inevitably call me for a time from His Majesty's service in his Royal Gardens at Kensington; but should His Majesty be graciously pleased to think my services would be productive of a national good, and will condescend to permit me to be absent, I shall with the greatest pleasure and alacrity engage in the undertaking.

I beg permission to lay before your Honourable Board several specimens of parts of trees which have been injured in a manner similar to those you have alluded to; others which have been healed by the method I have before mentioned. But the most effectual means of demonstrating the utility of this application, is the many fruit and forest trees now growing in His Majesty's Royal Gardens at Kensington, which I shall be happy to show you.

Your Honourable Board, considering the shortness of time, will, I trust, make every allowance for any inaccuracy in this answer to the letter you favoured me with, and permit me to subscribe myself,

With the greatest respect,

Your most obedient,

Humble Servant,

WILLIAM FORSYTH.

*To the Honourable the  
Commissioners of the Land Revenue.*

*Land Revenue Office, April 25, 1789.*

SIR,

WE have received your letter of yesterday's date, which contains a very clear and satisfactory answer to our enquiries respecting the effects of injuries done to the bark of Oak trees, and the means of preventing damage to the timber from that cause; and the specimens sent with your letter afford the most convincing proofs both of the destructive consequences arising from even slight injuries to the bark, when no means are used to prevent them, and of the efficacy of your discovery for preventing and curing defects in timber proceeding from that source: but we observe that you have not given an answer to our enquiry as to the expence which the application of the remedy you have discovered would be attended with, by the hundred, or thousand, or any given number of trees, in case there should be occasion to apply it to a very considerable number. We therefore repeat our request, that you will be so good as to inform us, as nearly as you can, whereabouts would be the expence of such application, including labour, materials, and all incidental charges; but exclusive of any reward to yourself for disclosing the

Composition for the benefit of the public, which we conceive should be given separately.

We are, Sir,

Your most obedient Servants,

JOHN CALL,  
JOHN FORDYCE.

*Mr. William Forsyth.*

---

No. III.

*To the Honourable the Commissioners of the Land Revenue.*

*Royal Gardens, Kensington, April 28, 1789.*

HONOURED SIRS,

I PRESUME I need not again assign the reason why I omitted in my former letter mentioning the expence which will be incurred by cutting out the injured parts of the trees, and the application of my Composition. I have endeavoured to think of every probable charge that will accrue; and, upon an accurate calculation, I am convinced

it will not exceed sixpence per tree. It may not be improper here to observe, that this calculation includes the labour of the men for the operation, the Composition, and the application of it; and also an after review, that the healing of the trees is going on well; but I should also observe, that in this expence I have not put down any thing for myself, leaving that wholly and altogether to your further consideration.

I am, honoured Sirs,

With great respect,

Your most obedient,

Humble Servant,

WILLIAM FORSYTH.

No. IV.

*July 24, 1789.*

**RESOLVED,**

THAT an humble Address be presented to His Majesty, that he will be graciously pleased to give directions for making such enquiries as shall be thought necessary for the purpose of ascertaining the efficacy of a remedy invented by William Forsyth, for curing defects in trees, arising from injuries in the bark ; and in case the same shall appear likely to be of public utility, to order such recompence to be made to the same William Forsyth, on the disclosure thereof, as His Majesty shall judge proper ; and to assure His Majesty this House will make good the same.

No. V.

*Land Revenue Office, Scotland-Yard,  
Dec. 11, 1790.*

MY LORDS AND GENTLEMEN,

HAVING represented to the Lords Commissioners of His Majesty's Treasury, that in pursuance of their Lordships' desire, we had written to the several noblemen and gentlemen mentioned in the list, of which a copy was sent to each of you, requesting to know whether they would have the goodness to make the necessary examinations and enquiries, to ascertain the effect of the experiments made by Mr. Forsyth, of the Composition discovered by him for curing defects in trees; and that twelve of those noblemen and gentlemen, hereunder named, and to whom this letter is addressed, had signified their willingness to assist in the proposed examination: we have now the honour to inform you, that their Lordships have been pleased to signify to us, that they approve of the examination being made by those noblemen and

gentlemen, or any seven or more of them; and to request that you will be pleased to take such steps as you shall think necessary for ascertaining the efficacy of the said Composition for curing injuries and defects in trees, and to address the result of your examination to the Lords of the Treasury.

Among the uses to which the Composition in question is said to be applicable, that which appears to us more immediately connected with the objects referred by Parliament to our consideration is, the cure of injuries and defects in forest trees, especially the Oak : and we beg leave particularly to recommend it to you to examine.

Whether the Composition appears to be efficacious for the purpose of restoring the bark of an Oak tree which has been either cut or accidentally torn off, so as to prevent such injuries or defects in the timber, as are commonly found to proceed from that cause.

And whether the application of the Composition to the parts of forest trees where limbs or branches have been cut or torn off, appears to be efficacious for the preventing or curing injuries and defects in timber, proceeding from that cause ?

We presume, with great deference, that you will think it proper to point out any other uses to which the Composition may appear to you to be applicable, with advantage to the public ; and we request that you will be pleased to favour us with

a copy of your resolutions, or report to the Treasury thereon.

We have the honour to be,  
My Lords and Gentlemen,  
Your most obedient,  
Humble Servants,

CHARLES MIDDLETON,  
JOHN CALL,  
JOHN FORDYCE.

*The Marquis of Abercorn,  
Earl of Upper Ossory,  
Lord Viscount Barrington,  
Lord Frederick Campbell,  
Sir George Yonge, Bart., K. B.  
John Rolle, Esq.  
Philip Stephens, Esq.  
C. M. Pierrepont, Esq.  
William Pulteney, Esq.,  
Robert Barclay, Esq.  
Hans Sloane, Esq.  
William Mainwaring, Esq.*

*To the Lords Commissioners of His Majesty's Treasury.*

MY LORDS,

HAVING met on Saturday, at Kensington, in compliance with the desires of your Lordships, communicated to us by the Commissioners of the Land Revenue, we endeavoured to take every measure for the investigation requested of us, that the time and circumstances permitted; and we conceive that the best and most satisfactory mode of reporting to your Lordships the result of that investigation will be, to specify, as shortly as may be, the steps we took; the observations we made; and our opinions, founded both upon what we ourselves saw, and upon such documents as appeared to us authentic and convincing.

After referring to the last letter, addressed to us by the Commissioners, in order that we might keep in view, as much as possible, the objects more particularly recommended to our attention, we proceeded first to read a statement by Mr. Forsyth of the properties of his Composition, and then to inspect and examine the various specimens and documents laid before us by him, tending to prove and illustrate those properties.

Our investigation, thus far, having proved as satisfactory as the nature of it admitted, we thought it right to require Mr. Forsyth to shew us such trees in Kensington Gardens as (having been injured or decayed by whatever cause) had

been benefited by the application of this Composition; and we desired him to shew us what specimens he could of such trees in all the stages of their amendment and recovery. In consequence of this requisition, we were conducted to many forest trees of different kinds (viz. Elms, Limes, and Horse Chesnuts), in which holes and wounds, in some instances several feet in length, and of a considerable width and depth, had been completely filled up with sound wood, so as the outline of the wound remained barely discernible in the bark. We examined many others in an evident state of progress towards a similar cure; and we could not discover any one of the experiments that fell under our observation, of which we had the least reason to doubt the success. We examined also several experiments upon trees, which, standing near each other, had been cut down, and to the stems of which the Composition had been applied, while the others had been left to nature: the uniform result of these experiments appeared, that those stems to which the Composition had been applied had shot up into healthy vigorous trees, in far less time than we should have conceived possible; while those left to unassisted nature had only produced irregular, unhealthy shoots, and were apparently in a state of decay. Several experiments had also been made on decayed and hollow stumps (where little or nothing but bark remained) of Elms of very considerable size and age: from these stumps, by the

application of the Composition, healthy trees have issued, which have, in the space of five, six, seven, or eight years, attained to a size and height which, it appears to us, that trees sown or planted seldom attain to in thrice the time. With a view to ascertain, as far as was in our power, the quality of that wood which by the application of the Composition had been formed in the decayed and injured parts of trees, we cut pieces of it out, and compared them with other pieces cut out of the original wood of the same trees; and, after as accurate a secreting and comparison as we were enabled to make, we could not discover any difference either in the colour or texture.

Upon our observing to Mr. Forsyth, that we had not yet seen any specimens of the operations of his Composition upon Oak trees, he informed us, that, having at first confined his experiments to other trees, which were in a state of greater decay, he had none of the same date (*viz.* from two to eight years) to shew us, but that we might see many specimens of near two years' standing, equal in their progress to the rest; accordingly we examined various experiments upon Oaks; of which the progressive state was so perfectly similar to that of the other species of trees, that we should not be justified in any doubt upon that head; the event, also, of comparing the new wood with the old was the same.

To report at large our observations upon the effects of the Composition applied to different fruit

trees, would be little more than a repetition of what we have already said; the time of the year would only allow us to remark the rapid growth of the branches and shoots wherever the Composition had been applied to the most decayed and injured stems.

We deem it unnecessary to enter into any detail of the collateral information and documents which confirmed the impressions resulting from our personal observations, persuaded that your Lordships will believe we omitted no means in our power to form our judgments.

We will, therefore, only add, that, from all we saw and heard, we have reason to believe, and consequently do not hesitate to express our conviction, that Mr. Forsyth's Composition is a discovery which may be highly beneficial both to individuals and the public,

We have the honour to be

Your Lordships' obedient Servants,

ABERCORN,  
FREDERICK CAMPBELL,  
WILLIAM PULTENEY,  
CHARLES PIERREPONT,  
HANS SLOANE,  
GEORGE YONGE,  
PHILIP STEPHENS,  
ROBERT BARCLAY,  
JOHN ROLLE,  
WILLIAM MAINWARING.

No. VI.

IN consequence of an Address of the House of Commons to His Majesty, and of an examination made by —

THE MARQUIS OF ABERCORN,  
 LORD FREDERICK CAMPBELL,  
 WILLIAM PULTENEY, ESQ.  
 CHARLES PIERREPONT, ESQ.  
 HANS SLOANE, ESQ.  
 SIR GEORGE YONGE, BART.  
 PHILIP STEPHENS, ESQ.  
 ROBERT BARCLAY, ESQ.  
 JOHN ROLLE, ESQ., AND  
 WILLIAM MAINWARING, ESQ.

and their report to the Lords Commissioners of His Majesty's Treasury, respecting the efficacy of a Composition discovered by Mr. William Forsyth, for curing injuries and defects in trees; His Majesty has been pleased to grant a reward to Mr. Forsyth, for disclosing the method of making and using that Composition; and the following directions for that purpose are published accordingly:—

*Royal Gardens, Kensington, May 11, 1791.*

*Directions for making a Composition for curing Diseases, Defects, and Injuries, in all Kinds of Fruit and Forest Trees, and the Method of preparing the Trees and laying on the Composition, by WILLIAM FORSYTH.*

TAKE one bushel of fresh cow-dung, half a bushel of lime-rubbish of old buildings (that from the ceilings of rooms is preferable), half a bushel of wood-ashes, and a sixteenth part of a bushel of pit or river sand: the three last articles are to be sifted fine before they are mixed; then work them well together with a spade, and afterwards with a wooden beater, until the stuff is very smooth, like fine plaster used for the ceilings of rooms.

The Composition being thus made, care must be taken to prepare the tree properly for its application, by cutting away all the dead, decayed, and injured part, till you come to the fresh sound wood, leaving the surface of the wood very smooth, and rounding off the edges of the bark with a draw-knife, or other instrument, perfectly smooth, which must be particularly attended to; then lay on the plaster about one-eighth of an inch thick, all over the part where the wood or bark has been so cut

away, finishing off the edges as thin as possible: then take a quantity of dry powder of wood-ashes mixed with a sixth part of the same quantity of the ashes of burnt bones; put it into a tin box, with holes in the top, and shake the powder on the surface of the plaster, till the whole is covered over with it, letting it remain for half an hour, to absorb the moisture; then apply more powder, rubbing it on gently with the hand, and repeating the application of the powder till the whole plaster becomes a dry smooth surface.

All trees cut down near the ground should have the surface made quite smooth, rounding it off in a small degree, as before mentioned; and the dry powder directed to be used afterwards should have an equal quantity of powder of alabaster mixed with it, in order the better to resist the dripping of trees and heavy rains.

If any of the Composition be left for a future occasion, it should be kept in a tub, or other vessel, and urine of any kind poured on it, so as to cover the surface; otherwise the atmosphere will greatly hurt the efficacy of the application.

Where lime-rubbish of old buildings cannot be easily got, take pounded chalk, or common lime, after having been slaked, a month at least.

As the growth of the tree will gradually affect the plaster, by raising up its edges next the bark, care should be taken, where that happens, to rub it over with the finger when occasion may require (which is best done when moistened by

rain), that the plaster may be kept whole, to prevent the air and wet from penetrating into the wound.

WILLIAM FORSYTH.

William Forsyth, of Kensington, in the county of Middlesex, Gardener, maketh oath, and saith, that the foregoing is a true account of the method of making and using the Composition discovered by him for curing diseases, defects, and injuries, in fruit and forest trees: and which Composition was applied by him to the trees in His Majesty's Gardens at Kensington, shewn to the noblemen and gentlemen to whom it was referred to examine the efficacy of the said Composition.

WILLIAM FORSYTH.

*Sworn at the Land Revenue Office, in Scotland Yard, the  
Eleventh Day of May, 1791, before Us,*

CHARLES MIDDLETON,  
JOHN CALL,  
JOHN FORDYCE.

## No. VII.

*Additional Directions for making and using the Composition.*

To the foregoing directions for making and applying the Composition, it is necessary to add the following : —

As the best way of using the Composition is found, by experience, to be in a liquid state ; it must, therefore, be reduced to the consistence of a pretty thick paint, by mixing it up with a sufficient quantity of urine and soap-suds, and laid on with a painter's brush. The powder of wood-ashes and burnt bones is to be applied as before directed, patting it down with the hand.

When trees are become hollow, you must scoop out all the rotten, loose, and dead parts of the trunk till you come to the solid wood, leaving the surface smooth ; then cover the hollow, and every part where the canker has been cut out, or branches lopped off, with the Composition ; and, as the edges grow, take care not to let the new wood come in contact with the dead, part of which it may be sometimes necessary to leave ; but cut out the old dead wood as the new advances, keeping a hollow between them, to allow the new wood room to extend itself, and thereby fill up the

cavity, which it will do in time, so as to make as it were a new tree. If the cavity be large, you may cut away as much at one operation as will be sufficient for three years. But in this you are to be guided by the size of the wound, and other circumstances. When the new wood, advancing from both sides of the wound, has almost met, cut off the bark from both the edges, that the solid wood may join, which, if properly managed, it will do, leaving only a slight seam in the bark. If the tree be very much decayed, do not cut away all the dead wood at once, which would weaken the tree too much, if a standard, and endanger it being blown down by the wind. It will, therefore, be necessary to leave part of the dead wood, at first, to strengthen the tree, and to cut it out by degrees as the new wood is formed. If there be any canker, or gum oozing, the infected parts must be pared off, or cut out with a proper instrument. When the stem is very much decayed, and hollow, it will be necessary to open the ground and examine the roots; then proceed as directed for hollow Peach-trees; [see PLATES II. and V., which shew the manner of preparing hollow trees, and also the growing of the wood.]

Some months before the publication of the "Observations on the Diseases, &c. in Fruit and Forest Trees," I had tried the Composition in a liquid state, but did not think myself warranted to make it public until I had experienced its effects through

the Winter. The success answered my most sanguine expectations ; and I have used it in that way ever since. By using the Composition in a liquid state, more than three-fourths of the time and labour is saved ; and I find it is not so liable to be thrown off as the lips grow, as when laid on in the consistence of plaster : it adheres firmly to the naked part of the wound, and yet easily gives way as the new wood and bark advance.

The first time that I tried the Composition in a liquid form, was upon an Elm which had been planted about twenty years. It had been very much bruised by the roller, had several cavities in it, and was very much bark-bound besides. Having prepared the wounds, and applied the Composition with a painter's brush, I took my knife and scarified the tree in four places ; I also shaved off, with a draw-knife, all the cankerous outer bark, and covered the whole tree with the Composition, shaking the powder of wood-ashes and burnt bones all over it. A very heavy rain began in the evening, and continued all night ; yet, to my great surprise, in the morning, I found that only some of the powder, which had not had time to dry and incorporate with the Composition, was washed off. I now repeated the powder, and without any thing more being done to the tree, the wounds healed up and the bark was restored so completely, that, three years ago, it could hardly be discerned where the wounds had been.

The scarifications had also disappeared. Some of the wounds were thirteen inches long, eight broad, and three deep. Since the time when it was scarified, the tree has increased ten inches more in circumference than a healthy tree planted at the same time with it about sixteen feet distant, which was not scarified.

# **SUPPLEMENT.**

## SUPPLEMENT.

---

*Success of several Experiments since the Publication of  
“ Observations on the Diseases, Defects, &c.”*

SINCE I published my “ Observations on the Diseases, Defects, and Injuries in Fruit and Forest Trees,” I have been assiduous in making experiments for the sake of improvement. A great many hollow trees that had, when I took them in hand, little more than the bark remaining sound, have within these few years been entirely filled up ; others, that were headed down within a few feet of the ground, have their stumps now completely covered by the leading shoots, forming handsome trees ; and the places where they were headed are only discerned by a faint cicatrice. Of a great many, I shall only particularize a few instances.

A Lime tree, about eighteen inches in diameter, whose trunk was decayed and hollow from top to bottom, to which, after cutting out the decayed

wood, I had applied the Composition about sixteen years ago, was cut down last year on purpose to examine the progress it had made in the interior part, and was found entirely filled up with new sound wood, which had completely incorporated with what little old wood remained when I first took it in hand. The body of this tree I had cut in short lengths, which I have now in my possession, to shew to any gentleman who wishes to be convinced of the fact. An old Elm whose inside was totally decayed, and out of which, at different times, were taken two large cart-loads of rotten wood, has made shoots upwards of twenty feet high in the course of six years. Another Elm, on the Palace-green, which was headed about twenty feet from the ground, has produced a shoot forty-six feet high, and five feet nine inches in circumference. A Lime, cut down near the ground, has now a shoot twenty feet high, which entirely covers the stump, forming a fine tree twenty-one inches in circumference. A Sycamore, treated in the same manner, is now thirty feet high, and twenty-six inches in circumference. Another is thirty feet high, and two feet in circumference. These are now fine thriving trees, and the cicatrices hardly discernible.

A Horse Chesnut headed down has produced, from its hollow stump, four fine shoots, one of which is cut down; the other three are upwards of thirty feet high, and one of them is twenty-six inches in circumference. Two of the remaining

three are to be cut down, leaving only one to form the body of the tree. A Lime, whose hollow part is eleven feet high, is also filling up; the tree is a foot in diameter. A decayed part, four feet high and twenty-eight inches broad, in a large Elm, is now filling up rapidly with sound wood. About two feet and a half in length on one side, which was for some time left to Nature, still continued to decay till the Composition was applied; new wood and bark are now forming. An Elm, at the back of the old fruit-room, near the garden wall, which was entirely hollow, was also headed down; the new head now spreads about twenty-four feet, and is eighteen feet high. Another large hollow Elm, near the last, was headed down; it afterwards produced a shoot sixty feet high, and three feet and a half in circumference: the hollow was upwards of two feet in diameter. There are a great many other Elms, some of which had wounds ten feet long and two feet broad, now entirely filled up; besides many Sycamores, Oaks, and other forest trees, all restored to a flourishing state, by having the dead wood cut out, and the Composition applied. An oak that was headed down about six years ago is represented in PLATE XII.

In hollow trees, the rotten and decayed wood must be cut out at different times, as the new wood comes in contact with it; but great care must be taken not to cut out too much at once, but to leave enough to support the tree and prevent it from

being blown down by high winds, till the new is strong enough for that purpose: the remainder may then be cut out.

A number of instances of the success attending my method of pruning and training might be adduced; but I shall notice only the following.

Mr. Aberdeen, gardener to John Sullivan, Esq. at Richings, near Windsor, has followed it for some time with great success both in the house and on the natural wall.

Having heard for several years of the very fine and large crops that were produced in the forcing-houses belonging to John Julius Angerstein, Esq. at Woodland-house, on Blackheath, I was induced to take a journey thither, in company with John Wedgwood, Esq. to see what method was pursued to obtain such crops. On enquiry, Mr. Stuart, the gardener, candidly told me, that several years ago he had been at Kensington Gardens, where he saw my method of pruning and training, and was convinced of its advantages above the old, and had adopted it with great success. Indeed, there were, at the time I was there, the finest and largest crops of Grapes that I had ever seen in any forcing-houses. Two houses, in particular, were covered from top to bottom with fine Grapes, and the Vines trained in the serpentine manner.

John Wedgwood, Esq. of Cote House, near Bristol, a gentleman who is much attached to gar-

dening and planting, tells me, that he has practised my mode of pruning and training fruit trees, particularly Peaches and Nectarines, in his houses; and that he is highly pleased with the method, which has been attended with great success.

Lord Frederick Campbell has lately favoured me with a list of eighty-five fruit trees, of different kinds, that were headed down in his garden at Coomb-bank, in Kent, in the years 1798 and 1799; and afterwards trained and pruned according to my method: many of them, before heading down, were in a very cankerous, unfruitful state, and overgrown with moss; these are now in a fruitful, healthy, and flourishing condition; some of the Espaliers have made shoots from two to three yards long and upwards. These trees were cut and prepared by Mr. Williams, who had been for some time accustomed to my way of treating such trees, and whom I recommended to his Lordship as a gardener. These trees are very proper patterns for any gentlemen in the neighbourhood, who wish to give the Composition, and method of training and pruning, recommended in this Treatise, a fair trial.

Several successful trials have also been made at the Duke of Dorset's seat, at Knowle, in Kent, at Hatfield House, the seat of the Marquis of Salisbury, and at a great many other places; and experiments are now making at Sir Henry Strachey's, at Rook's Nest, near Godstone, in Surrey.

ALTHOUGH I do not mean to enter at large on the culture and management of forest-trees; yet, as the following observations on raising Oaks, and directions for planting Chesnuts for underwood, may be of considerable service I shall, without any further apology, lay them before my readers.

*The best Way of raising Oaks.*

It is a generally received opinion, that when an Oak loses its tap-root in transplanting, it never produces another; but this I have proved to be a mistake, by an experiment which I made on a bed of Oak plants in the year 1789. I transplanted them into a fresh bed in the forementioned year, cutting the tap-roots near to some of the small side-roots or fibres shooting from them. In the second year after, I headed one-half of the plants down, as directed for Chesnuts, and left the other half to nature. In the first season, those headed down, made shoots six feet long and upwards, and completely covered the tops of the old stems, leaving only a faint cicatrix, and had produced new tap-roots upwards of two feet and a half long. One of these trees I left at the Land Revenue Office, for the inspection of the Commissioners, and to shew the advantage of transplanting and heading down young Oaks, when done in a proper manner. By this mode of treatment, they grow more in one

year than in six, when raised in the common way. The other half of the plants, that were not headed down, are not one-fourth the size of the others. One of the former is now eighteen feet high, and, at six inches from the ground, measures fifteen inches in circumference; at three feet from the ground, ten inches; and at six feet, nine inches and a half; while one of the largest of the latter measures only five feet and a half high, and three inches and three quarters in circumference, at six inches from the ground. This is a convincing proof that transplanting and heading down Oaks is the most successful and advantageous way of treating them; and by it they are sooner out of danger from cattle, as well as from vermin, which are frequently very injurious to young trees.

*Of raising Chesnuts for Underwood.*

As the Chesnut is the best and most durable wood for stakes, hop-poles, &c. I shall give some directions how to plant them to the best advantage for copse wood.

For this purpose the ground should be trenched, or ploughed, and well summer fallowed. After the fall of the leaf, plant the young trees in the Quincunx order, in rows six feet apart, and at the distance of six feet in the rows from plant to plant. If you are forming large plantations, the most expeditious way will be to plant after the plough,

treading the earth firmly about the roots of the plants. It will be necessary to form basins round the plants on purpose to mulch them, if it should happen to be a dry season the first Summer after planting. It may, perhaps, be a saving of time to put the plants in loosely at first, that you may be able to keep up with the plough, and to return afterwards to tread the mould and form the basins for mulching.

When the trees are become fit for poles, every other one may be cut down almost close to the ground throughout the plantation; always observing to cut in a sloping manner, and as near to an eye as may be. Those that you intend for timber should be left in every other row, which will leave them twelve feet apart every way: but if the soil be rich and deep, it may be necessary to leave them twenty-four feet apart. In many countries, particularly Hertfordshire, the underwood is more valuable than timber; in that case it will be more judicious to leave but few trees for that purpose: in the mean time the underwood will amply repay you for the expence of planting, &c. besides the rent of the ground, while at the same time you have a sufficient crop of timber on the ground. In Kent they generally plant out Chesnuts and Ash for hop poles at three years old, and cut them fourteen years after, which makes, in all, seventeen years before they are fit to cut; and they bring from one guinea and a half to two guineas per

hundred; but if they were raised from large stools, properly cut, and the Composition applied, they would be fit for cutting in less than one-third of that time; and of course, the value of the land would be tripled.

LETTERS

ON THE

EFFECTS OF THE COMPOSITION

*IN ALL CLIMATES.*

---

THE following letters, &c. are inserted to show that the Composition, when properly applied, is found to be equally efficacious in all climates, soils, and situations. Indeed, all who have given it a fair trial are so fully convinced of its utility, that many noblemen and gentlemen have sent their gardeners to me for instructions. The Chevalier D'Almeida, the Portuguese Ambassador, had a person sent from Portugal for the same purpose; and some Polish noblemen, who had seen the trees in Kensington Gardens, were so fully convinced of the great advantage to be derived from the application of the Composition, as to send a man for instructions, that he might introduce the practice into Poland.

*Copy of a Letter from the Œconomical Society of  
St. Petersburg.*

*Imperial Corps of Land Cadets, in St. Petersburg,  
January 9. 1792.*

SIR,

As a member of the Œconomical Society of St. Petersburg, his Excellency Count Anhalt solicits me to express, in your own language, the pleasure which the communication of your useful discovery has given him, and the learned body over whom he so worthily presides. The Count has already taken the necessary steps, by desire of the Society, to have your little dissertation translated and printed in the Russian language, in order to diffuse the advantage it holds out as widely as possible, over this vast empire. I am happy in the opportunity his commission offers, of expressing likewise, individually, the satisfaction I have received, as a countryman and lover of Botany, from the perusal of your sagacious application of the Chirurgical art to vegetation; and must own, that your extirpation of the diseased parts, and the use of an unguent to ward off the noxious action of the air and humidity, during the exertions of nature to repair loss of substance, and the languid circulation of the vegetable juices, appear to me highly judicious. The analogy in certain respects between the inferior order of *beings*, so particularly your care, and the more animated

link of the great chain of Creation, seems to become every day more and more apparent. Nay, if we are to credit the ingenious Author of the *Philosophy of Natural History*, lately published in Edinburgh, it is not a little evident; and, indeed, the great number of curious facts and observations which he has brought together, render the phrase which I have used above, much less improper than it would have otherwise appeared on the face of the case. All these considerations then make me see, with the more pleasure, the sagacious application of at least one branch of the healing art to certain diseases of vegetables, to the advantage of the world in general, and the British Navy in particular, which must gain infinitely by the preservation and health of British Oak, unrivalled for the noble purpose to which it is applied.

I have still to congratulate you on your becoming, so deservedly, a member of our Society; for sure no treatise ever laid before us promised a wider field of public and private œconomy, and of course none ever came more immediately under the spirit and purport of our institution.

I am, Sir,

With hearty wishes for the success and extended range of your pursuit,

Your most obedient, humble Servant,

(Signed)

MATTHEW GUTHRIE.

*To Mr. Forsyth, Kensington.*

P. S. As the extremes of our climate may produce cases which are not likely to happen in your temperate island, Count Anhalt will be happy to see more observations on such accidents in any future letter you may address to the Society. A paper of mine on the Russian climate, in the second volume of the Philosophical Transactions of the Royal Society of Edinburgh, may probably afford you all the information necessary to judge of what modification your system may require in this country, although I do think it applicable every where, with possibly, some little alteration in the consistence of your plaster, to suit extremes of heat and cold. This letter being of a public nature, intended to testify the sense of the Economical Society of Petersburg, on your useful discovery, you may make what use of it you please.

*Copy of a Letter from George Sullivan Marten, Esq.*

*Enston, Oxfordshire, July 30. 1800.*

SIR,

UNDERSTANDING there exists some doubt how far your vegetable plaster answers in hot climates, I cannot in justice hesitate to inform you, that it was in constant and successful use not only in my own garden, in the district of Trinsivelly, four hundred miles South of Madras, but also in the Company's Cinnamon Plantation, which I had the pleasure of forming there, and where, from the method of cultivating that spice, the trees are always cut down to stumps. Your plaster at these times was always applied, which stopped the bleeding, and hastened out the shoot (from whence the best Cinnamon is taken) much quicker than the former mode (and which is still practised in Ceylon, I believe) of heaping the earth over them. Nor was my experience confined; for, when I quitted India, in October, 1798, I left one hundred and fifty thousand trees and plants in the Trinsivelly Plantations, all of which I had planted from the seed of two trees brought from the

Island of Ceylon, by Mrs. Light, which are yet flourishing, I dare say, in the Commercial Resident's Garden.

I likewise applied your plaster with equal success to the fruit-trees of the country. But to an old Pumbilmos, or Shaddock tree, which was almost throughout decayed, and which I had to fill up with the plaster after the dead wood was taken out, it produced wonderful renovation. I derived too much benefit from this Composition to finish without assuring you, that I will with much pleasure, give you any further information as to its success in hot countries, that came within my observation during the use of it, for several years, in the district of Trinsivelly.

I am, Sir,

Your most obedient Servant,

(Signed)

GEORGE SULIVAN MARTEN.

*To Mr. Forsyth.*

*Copy of a Letter from John Wedgwood, Esq.*

*Cote House, Nov. 14. 1800.*

DEAR SIR,

WHEN you were with me, you expressed a wish to have the number of Peach and Nectarine trees which I had on my walls, that had been dressed with your Composition. These trees were part of a set which I bought in a lot, and which had been left to grow rude against an old wall, so that they appeared to be gone past all cure. Many were eaten up with the canker, and many were become so naked at the bottom that they gave but little room to imagine they could be brought into any form. I planted them against my walls in the beginning of the year, where they were left unpruned till the middle of May. The gardener then gave them a severe cutting in, and, as he went on, constantly dressing them with your Composition, carefully eradicating all the canker. I can now safely say, that they are as free from canker as any trees I ever saw, and full of fruit-bearing wood, many of them brought into excellent form, and all of them, except some few which died in the summer, promising to make very useful and profitable trees ; so that if I had occasion to new-stock my walls, I should as willingly purchase another

such lot as buy regular trained trees from a nursery. Provided the roots are good, I am convinced from experience, that the older the tree the more profitable it will be, as in the case of the trees above described; all the young shoots are covered with blossom buds in great profusion.

The following is a list of the trees, and the aspects of the walls on which they are planted.

19 Peach and Nectarine trees on a new wall by  
the hot-house, East aspect.

16 do. — do. — on another, same aspect.

19 do. — do. — on the same aspect.

5 do. — do. — on a South aspect.

2 do. — do. — on another South wall.

4 do. — — — on another South wall.

---

65 in all.

---

These are exclusive of many trees that were on the walls before, and which have been much benefited by being dressed with your Composition. I am so fully aware of the excellence of the Composition, that I do not permit the gardener to prune any plants without immediately using it. If you think these remarks can be of any service, you have my permission to make any use of them.

I am, dear Sir,

Your's sincerely,

(Signed)

JOHN WEDGWOOD.

*Extract of a Letter from Thomas Davis, Esq. Author of the  
Agricultural Survey of Wiltshire.*

June 28. 1801.

“ I was happy in having an opportunity the other day of shewing the effects of your plaster (in recovering the bark of Oak trees of 400 or 500 years old, which had begun to rot upwards from the ground, and is now recovering downwards very rapidly) to *Lord Spencer*, who was both pleased and astonished with it.

“ You may at any time refer to *me* for proofs if you want them. I made a bold experiment seven years ago on an oak tree forty feet high, and  $16\frac{1}{2}$  feet round, worth 80*l.* at least to a *carpenter* to cut to pieces, and such a tree as the King has not ten in his dominions. There was a craze in the side of it, which looked like a shake, and spoiled its beauty. I cut out the bark on each side the fissure, so as to make the opening six or seven inches wide. I coated it well with plaster, and it is now perfectly united and sound.

“ In the annexed Figure, *a* represents the Fissure which separated the *Bark*, but did not affect the wood.”

*Directions for heading down Orange Trees.*

Just as the manuscript was going to the press Mr. Rademaker, the Portuguese agent in London, called and told me, that he had received a letter from the Chevalier d'Almeida, the late Ambassador from Portugal at this court, informing him, that on his return home, he had found the Orange trees on the Prince of Brazil's Plantations in a very unhealthy and decayed state; and requesting him to apply to me for some of the Composition, and a copy of the Pamphlet "On the Diseases, &c. in Fruit and Forest Trees," as he wished to make a trial of it on the trees of that country.

Accordingly, I have sent a cask of the Composition, with directions for preparing the trees and laying it on.

When it is found necessary to head down Orange trees, I would advise not to cut them quite down to the stem; but to leave two or three inches of the branches; some more, some less; always remembering to cut near to a joint, and in such a manner as to form a handsome head, and to apply the Composition immediately. In doing this, however, it will be necessary to leave a few young shoots to draw up the sap. If the trees are infested with insects, the stems must be washed with soap-suds and urine, and well scrubbed with a hard brush.

About twelve years ago the Orange trees in the green-house in Kensington gardens were so much

infested with a species of Coccus, that I was obliged to head them all down, and clean off the insects as above directed; applying the Composition immediately after. These trees throve amazingly; and in three years, without any bottom heat, the heads were as large as before they were cut; and they still continue in a flourishing and fruitful state.

I would advise to rub off the side shoots, as directed for other fruit trees, and to keep the heads thin of wood.

I thought it proper to insert the above for the information of those who have Orange trees in this country, as well as for those who have them abroad.

**EXPLANATIONS**  
**OF THE**  
**ENGRAVINGS.**

## EXPLANATION OF PLATE I.

---

### *Fig. I.*

REPRESENTS an old Apricot-tree, after the last pruning in Summer, in the fourth year after heading down. The lower part of the trunk is represented as covered with a rough bark, which must be pared off when it happens to be cankerous.

*a, a, a, a.* The cicatrices of the four different years' heading, which should be performed at the time of the Winter or Spring pruning.

*b, b, b.* Forked shoots which are laid in, in Summer, and cut off at *b* in the Winter pruning, that the leading shoots may be always left without forks.

As the small shoots *c, c, c*, from the stem, advance, the larger forked shoots should be cut out, as at *d, d, d*, to make room for them to be trained horizontally.

### *Fig. II.*

Is an old branch of an Apricot trained up according to the old method, leaving above three-

## EXPLANATION OF PLATE II.

---

### *Fig. I.*

AN old hollow Green-gage Plum-tree the second year after heading down. This tree was very much decayed, having only a few inches of sound bark ; many of the roots being also rotten and decayed were cut off, and an incision made at *a*, which produced a fresh root.

*b.* The first heading, close to a bud.

*c, c.* The new wood and bark growing over the hollow part *d*, which is covered with the Composition.

*e, e, &c.* Where the second year's heading was performed.

*f, f.* Where the foreright shoots are cut off during the Winter or Spring pruning.

*g, g, g, &c.* The fruit-buds for next year, as they appear after the foreright shoots are cut off, as at *f, f.*

### *Fig. II.*

A branch, on a larger scale, to show the manner of cutting those foreright shoots, which are full

of fruit buds. This should be done at *h, h*, but not till the fruit is set; they afterwards form into dugs, as *i, i*.

*Fig. III.*

An old branch, pruned in the common way, covered over with canker, and producing only small weak shoots, leaving the wall mostly naked.

## EXPLANATION OF PLATE III.

---

### *Fig. I.*

AN old hollow Peach-tree, after the last nailing in Summer, which had been headed down at *a*, four years ago. The hollow is covered over with the Composition, and now nearly filled up. The heading must always be done as near to a bud as possible.

*b, b, &c.* Where the forked branches are to be cut, when the small shoots *c, c, &c.* are far enough advanced, that these may be trained horizontally.

When a shoot has single fruit buds to the top, as at *d*, it must not be shortened, but laid in at full length; or, if not wanted, it must be cut clean out.

### *Fig. II.*

A branch on a larger scale.

*e, e.* Are double flower-buds, with wood-buds between them: the shoots should always be cut at such; but never at a single flower-bud, as at *f*; otherwise the shoot would die to the next wood-bud; and, if the pruning were done in a careless man-

*Fig. 2.*

ner, would endanger the whole shoot. Those above *f* are all wood-buds.

*Fig. III.*

A branch of an old Peach-tree pruned in the common way, which should be cut at *g*, and the young wood will soon cover the wall.

## EXPLANATION OF PLATE IV.

---

### *Fig. I.*

AN old Cherry-tree headed down at *c*. Before this, its branches were covered with the gum and canker, as *Fig. II*.

The foreright shoots should be tucked in, as directed for Pears; and at the fall of the leaf, or in the month of February, they should be cut at *a*; these form the fruit-buds *b, b, &c.* all over the tree.

*c, c, &c.* The cicatrices where the leading shoot was headed in different seasons.

*d, d.* The Composition applied where large limbs were cut off.

### *Fig. II.*

A branch of this tree before it was headed down.

*e, e, &c.* Branches injudiciously pruned in Summer; which brings on the death of the shoot, and afterwards the gum and canker on the tree.

*f, f, &c.* The gum and canker in the last stage, which corrodes the whole tree if not carefully extirpated.

*Plate V.*

**A STANDARD CHERRY.**

*Published Feb<sup>r</sup> 1<sup>st</sup> 1863, for Will<sup>m</sup> Forgyth Kensington.*

*G. B. G. 47*

*H. M. G. 47*

## EXPLANATION OF PLATE V.

---

AN old Cherry-tree, restored from two or three inches of live bark, taken from the wall, and planted out as a dwarf standard : now very fruitful.

*a, a.* The cicatrices where it was headed down the first and second time.

*b.* The hollow covered with the Composition, and now nearly filled up with sound wood.

## EXPLANATION OF PLATE VI.

---

### *Fig. I.*

AN old canker Apple-tree, headed down four years ago, now bearing great plenty of fine fruit.

*a.* Where it was first headed down.

*b* and *c.* Two wounds covered with the Composition, and now nearly filled up with sound wood.

The part of the trunk below *a* shews the canker state of the bark; which rough canker bark must always be pared off, otherwise it will infect the new.

### *Fig. II.*

A branch shewing the method of keeping a regular succession of bearing wood.

*d.* A branch, which has done bearing, to be cut at *e*, and which is succeeded by the branch *f*; when that also is tired of bearing, it is to be cut at *g*, and will be succeeded by the branch *h*; and when that also is worn out, it is to be cut off at *i*. By proceeding in this manner, you will always be able to keep a regular succession of fine bearing wood.

*Fig. 2.*

## EXPLANATION OF PLATE VII.

---

THIS Plate represents an old decayed Pear-tree, with four stems, which was headed down, all but the branch *C*, and the young wood trained in the common way, or fan-fashion.

*A, A, A.* Young wood producing the fine large fruit *B*.

*C.* An old branch pruned in the common way, having large spurs standing out a foot or eighteen inches, and producing the diminutive, kernally, and ill-flavoured fruit *D*, not fit to be eaten.

The two Pears *B* and *D*, represented in the Plate of their natural size, grew on the tree at the same time.

*a, a, a, &c.* Wounds in the stems of the tree, with the Composition applied, as they appeared when the edges of the bark began to grow over them.

## EXPLANATION OF PLATE VIII.

---

### *Fig. I.*

AN old decayed Beurré Pear-tree headed down at *f*, and restored from one inch and a half of live bark.

*a, a, a, &c.* The fruit-buds for the present year.

*b, b, b, &c.* Those forming for next year.

*c, c, &c.* The footstalks of the fruit of last year, on which are forming buds for bearing in the second year.

*d, d, &c.* The foreright shoots as they appear before they are cut off at *e*, in the Autumn or Spring pruning.

*d.* The manner of tucking in the foreright branches.

*f, f, &c.* Cicatrices of the different headings, which cause the leading shoot to produce horizontal shoots.

*g, g.* Large wounds, having the Composition applied, healing up.

### *Fig. II.*

AN old branch of the same tree before it was headed down, trained and pruned in the old way,

with spurs standing out a foot, or a foot and a half, from the wall ; and the rough bark, infested with a destructive insect, which is described, and a method of cure given, in CHAP. XXVIII. See Coccus and PLATE IX. *Fig. III.*

## EXPLANATION OF PLATE IX.

---

### *Fig. I.*

AN old Bergamot Pear headed down at the cicatrix *a*, taken from the wall and planted out as a dwarf standard.

*b.* A wound, covered with the Composition, where a large upright shoot was cut off, to give the leading shoot freedom to grow straight.

### *Fig. II.*

The different appearances of the insect so destructive to Pear-trees, mentioned in the CHAPTER ON INSECTS, under the head *Caterpillar*, p. 388.

This insect is inclosed in a case, and, when fixed on the leaf on which it feeds, appears as represented at *a, a, a*, which is about its natural size.

- b.* The case magnified.
- c.* The case, with the insect in motion, magnified.
- d.* The insect magnified.
- e.* The Moth.
- f.* The Chrysalis.
- g.* The Chrysalis magnified.

*Fig. 2.*

*Fig. 3.*

*Fig. III.*

The Coccus which infests Peach, Nectarine, and Pear-trees.

*a, a, a.* The insect, the natural size, on a branch of a Pear-tree.

*b, b, b.* The same magnified.

## EXPLANATION OF PLATE X.

---

*a, a, a, &c.* The young bearing wood of a Vine trained in a Serpentine manner, with the buds for the present year appearing. These shoots are generally cut out in the Winter pruning, as low as *c, c, c, &c.* to produce wood for next year.

The shoots *b, b, &c.* produce fruit in the usual manner, and also young wood for the following year, which must not be topped, but only have the side shoots picked off. Two or three of the strongest young shoots from each of those *b, b, &c.* will be sufficient, and they must be laid in at full length.

## EXPLANATION OF PLATE XI.

---

### *Fig. I.*

**GRAFTING in the rind, shoulder-grafting, or crown grafting.**

- a.* The stock-grafted.
- b.* The manner of raising the bark to receive the cion or graft.
- c.* The graft prepared for inserting.

### *Fig. II.*

**Cleft-grafting, stock-grafting, or slit-grafting.**

- d.* The stock grafted.
- e.* The stock prepared for receiving the graft.
- f.* The cion ready for inserting.
- d, d, d.* Different views of incisions made for the purpose of obtaining young wood.
- e.* A young shoot coming out at the lower part of the incision.

### *Fig. III.*

**Whip-grafting, or tongue-grafting.**

- g.* The stock grafted.
- h.* The stock prepared.
- i.* The graft prepared for inserting.

*Fig. IV.*

Inoculating or budding.

- k.* The manner of making the incision in the bark.
- l.* The bud inserted, and the bark laid over it.
- m.* A shoot, showing the manner of cutting off the buds.
- n.* A vessel, with a little loam, covered with wet moss, to stick the lower end of the shoot in, to keep it moist till used.
- o.* A bud taken off, and ready for inserting.

*Fig. V. and VI.*

Inarching, or grafting by approach.

- p.* Grafting on a stock in a pot.
- q.* Grafting on a stock growing, near the tree, from which it is to be grafted on.
- r, s.* The shoot and stock prepared.
- t, t.* Two branches inarched, where the natural ones had failed, now properly united with the body of the tree; the lower parts being cut off.
- u, u.* Two branches lately inarched for the same

purpose, and when properly united with the stem, are to be cut off at *u, u, u, u*.

*w, x.* The manner of preparing the stock and graft.

*v.* A natural shoot coming out where the branch was inarched the preceding year.

## EXPLANATION OF PLATE XII.

---

THIS plate represents an old stunted oak, which was headed down about six years ago. At that time it was full of wounds and blemishes, now nearly healed.

*a.* The place where the tree was headed, afterwards covered with the Composition.

*b, b, b.* Three young shoots produced since heading; there were several others, which were cut down as they advanced in growth: the two remaining side ones are also to be cut down, and only the middle one left, which will in time cover the wound *a*, and form a proper tree.

*c, c, c.* Remains of the old wounds, covered with the Composition, and now almost healed up.

**AN OAK.**

Fig. 6.

Fig. 12.

## EXPLANATION OF PLATE XIII.

---

- Fig.* 1. A tool for cutting out the dead and decayed parts of hollow trees. It has two wooden handles which may be of any convenient length.
2. Another tool with one handle for cutting out dead wood. This is made narrower than the former, and is to be used in places where *Fig.* 1. cannot be admitted.
3. A small saw with double teeth, thin on the back, for cutting off small branches, &c.
4. A long knife with a concave edge.
5. A pruning knife with a convex edge.
6. A tool in shape of a curry-comb for scraping moss, &c. off the stems and branches of trees: one of the scrapers has teeth; the other is plain. The back of this tool, and the edges of the scrapers, are a little concave.
7. A large double-toothed saw for cutting off large branches.
8. A tool resembling a hedge-bill for cutting branches, &c.

9. A small tool with only one sharp edge, to be used in places where *Fig. II.* cannot be admitted.
10. A knife, with two blunt edges, for scraping off rotten wood, &c. where the Composition is to be applied.
11. A large chisel with a strong plate of iron screwed upon the face of it, like a double iron for a plane, to prevent its running in too far where the tree is cross-grained.
12. A tool in form of a sickle, without teeth. This is to scrape stems and branches of trees on the side next the wall.

N. B. The tools represented by *Fig. 1, 2. 6.* and 11., have handles of different lengths, to be used as occasion requires.

Besides the above-mentioned tools, it will be necessary to have an adze, and chisels and gouges of different forms and sizes. Crooked chisels, like those used by carvers, will be found very useful in clearing small wounds from dead and rotten wood.

## P

PAPILIO, how to destroy, 396.

PEACHES, different sorts of, 36.

- Of the soil and borders for, 52.
- Draining a wet soil, 53.
- A sour wet clay, how to treat, 54.
- Of the choice of Peach-Trees, 54.
- Preparing the borders and planting, 54.
- Heading, topping, pruning, and training, 55.
- Pruning, training, and nailing of old Trees, 59.
- Of making incisions, 59.
- The canker, 60.
- The superfluous foreright shoots to be rubbed off and the small branches to be tucked in, 60.
- Of brushing off the leaves in Autumn, and unnailing the young branches, 61.
- Shreds that have been once used should be soaked in boiling hot soapsuds, to kill the eggs of insects before they are used again, 62.
- Of covering Peach-Trees, and thinning the fruit, 62.
- The great advantage of using the Composition, 63.
- Of watering and mulching, 63.
- The late side-shoots must be taken off, 64.
- Of picking off the leaves, 65.
- To procure a regular succession, 65.
- Sorts for North and East walls, 65.
- Peaches and Nectarines grown on the same tree, 66.

PEARS, different sorts of, 149.

**PEARS, Choice of Trees, and planting, 184, 185.**

- Heading, 187.
- Stunted trees, how to treat, 187.
- Pruning, 187.
- Cankery Trees, how to treat, 188.
- Experiments on unfruitful, old and decayed Trees, 189.
- A comparative statement of the produce of trees by the old and new way of pruning and training, 189.
- Description of an old Beurré Pear-Tree restored from  $1\frac{1}{2}$  inch of sound bark, 191.
- Of training trees that are headed down near to the place where they have been grafted, 192.
- Of the Canker and its Remedy, 193.
- Shortening the foreright shoots, 194.
- Of decayed and rotten roots, 194.
- Trenching the borders, 194.
- A remedy for stunted Pears, 195.
- The distance at which Pear-trees should be planted from each other, 196.
- Of borders, and the proper depth of mould, 197.
- How the Trees ought to be treated in a clayey soil, 198.
- Proper small crops for the borders, 198.

**PHALÆNÆ, how to destroy, 395.**

———— See BOMBYX.

**POISON, for Vermin. See RATS and MICE.**

**PLUMS, different sorts of, 14.**

- Choice of Trees, management of the Borders, and planting, 28.
- Heading down, 29.
- Distance at which Plum-trees should be planted, 29.

- PLUMS**, Training and shortening the leading shoot, 30.  
 ————— Preparing Wall-trees for standards, and transplanting them, 30.  
 ————— Trenching the Borders, 31.  
 ————— Of standards in Orchards, and Dwarfs in Gardens, 31.  
 ————— Of Cross-rows in Gardens, 32.  
 ————— Of pruning and restoring old and decayed trees, 32.  
 ————— Of foreright shoots, 33.  
 ————— Sheltering from frosts and cold winds, 34.  
 ————— The Composition ought always to be applied after the knife, 35.  
 ————— Of thinning the fruit, 35.  
**POTS**, number of, in a cast, 210. *note*.

## Q

- QUINCES**, best sort of, for the kitchen garden, 242.  
 ————— Propagation, planting, and pruning of them, 243.  
 ————— Rough bark, and bark-bound trees, 244.  
 ————— Should be planted at a distance from Apples and Pears, 244.

## R

- RASPBERRIES**, different sorts of, 263.  
 ————— Propagation and planting, 263.  
 ————— Watering and staking, 265.  
 ————— Pruning, 266.  
 ————— The time they will continue in a bearing state, 267.  
**RATS**, how to destroy them, 402.

## S

**SERVICE**, different sorts, 277.

———— The cultivated Service, 277.

———— How propagated, 278.

———— Training and pruning, 278.

———— The Mountain Service, or Mountain Ash, 279.

———— Its Propagation, 279.

———— Training, 279.

———— The Maple-leaved Service, 280.

———— Its propagation, training, &c. 281.

**SLUGS**, to destroy, 400.

**SNAILS**, to destroy, 400.

**SPHINX**, to destroy, 395.

**STOCKS** for grafting on, choice of, 308.

## T

**THRIPS**, how to destroy, 394.

**TRANSPLANTING** of old trees, 31. *note*.

**TREES**. For the Management of Fruit-trees. See **APPLES**, **PEARS**, **PLUMS**, &c.

———— Forest trees, how to manage. See "Observations on the Diseases, Defects, &c. of Trees."

**TRAPS** for catching Vermin. See **RATS** and **MICE**.

## V

**VEGETABLE Mould**, how produced, 145.

**VINES**, different sorts of, 199.

———— Of propagating Vines from seed, 210.

———— from cuttings, 213.

———— from layers, 216.

———— Of choosing Vines from the Nursery, 217.

**VINES.** Experiments and Observations on training and pruning of Vines, 219.

- Directions for training and pruning, 221.
- Use of the Composition after pruning, 226.
- Directions for watering Vines, 227.
- Of preserving Grapes from Flies, Wasps, &c. 228.
- Of picking off the leaves, 229.
- Gathering and preserving Grapes in Winter, 230.

## W

**WALNUTS,** different sorts cultivated in England, 298.

- Propagation and treatment in the Nursery, 299.
- Planting out, 300.
- Trimming, 300.
- Walnut-trees, excellent timber, 301.
- Value of Walnut-trees at Beddington Park, annually, 301. *note.*
- Leaves of, serviceable in destroying Slugs, 302.
- Method of keeping Walnuts, 302.

**WASH,** annual, for trees, 347.

**WASPS AND FLIES,** to destroy, 401.

**WATERING.** Directions for watering trees, 63.

- See also **MILDEW, APHIS, ACARUS, &c.** where directions are given for watering under different circumstances.

## CALENDARIAL INDEX.

---

### JANUARY.

**MAY** sow Carrots and Spinach on borders of Fruit Trees, 197.

Begin to prune Vines, if mild season, 213. 223. 498.

### FEBRUARY.

Scrape and wash Trees, 73. 256. 347. 362. 386. 390.

Prune Vines, 223.

Sow Vine Seeds in Pots on hot-beds, 210.

Make Layers from Vines, 216.

Begin to head Fruit Trees, x. & xi. (See APRIL.)

Prune Raspberries, 266.

Transplant Almonds, if wet soil, 283. (See OCTOBER.)

May sow Chesnuts, 294. and Walnuts, 299. (See OCTOBER.)

Begin to cut Cions, from lateral branches, for grafting, before the buds begin to swell, 306. 316.

Begin cleft grafting small Trees, 311, 312. 499.

Plant Fruit Trees in wet soils, 344.

Destroy Slugs, &c. 388. 400.

### MARCH.

Begin Pruning, 10. 55. 58. 422.

———— Cherries, 85. Pears, 192. Quinces, 243.  
Medlars, 246.

Still scrape and wash Trees, 73. 256. 347. 385. 390.  
 Begin to make incisions in cankered Trees, 85. 499.  
 Begin grafting large Trees in the Rind, 147. 311. 499.  
 Shorten leading Shoots of Pears, 193.  
 Begin to plant out seedling Vines against Walls, 212.  
 Plant Cuttings, or make Layers of Quinces, 243.  
 Sow Seeds of Currants, 259.  
 Lay down Raspberries, 264. and Nuts, 287.  
 Plant Cuttings of Mulberries, 274.  
 Cut the Stocks of former year's inoculated Trees, 320.

#### APRIL.

Head down Fruit Trees, especially fresh planted Trees,  
 from now till June, xi. xii. 7. 83. 138, 139. 187.  
 Shorten horizontal Shoots, 8.  
 Cover Fruit Trees in blossom, 11. 34. 62. 370.  
 Prune Peaches, 59. Nectarines, 72. Cherries, 83. Apples, 141. Almonds, 283.  
 Rub off superfluous fore-right Shoots, 58. 60. 88.  
 Make incision on old Peaches, 59.  
 Uncover Figs, if mild Season, 239. and Almonds, 284.  
 Destroy Caterpillars on Gooseberries, 256. and other Trees, 388. 395.  
 Inarch or graft by approach, 311. 313. 500.  
 Renew the Composition of the former Year, ix. x.  
 Cut out injured parts of Trees, 364. 366.  
 Cut dead Shoots and old fruit Stalks off Trees, xi. xii. 359. 363.

#### MAY.

Thin Fruit on Wall Trees, 35. 57. 73.  
 Rub off Spurs from Cherry Trees, 88.

Water to destroy the *Acarus* on Fruit Trees, 64. in Hot-houses and Frames, 378. 382.

Prune Apples, 141. Figs, 235. Mulberries, 275.

Burn Weeds, wet Straw, &c. &c. to the windward of Fruit Trees in blossom, to preserve from blight, &c. 347.

Wash Trees that are mildewed, 368.

Destroy Aphides, 375. Cocci, 385. Chermes, 394. Thrips, 394. *Phalænæ* and *Sphinx*, 395. *Papilio*, 396. *Cicadæ*, 397. Ants, 398. Slugs, 302. 388. 400.

## JUNE.

Pinch off the tops of leading shoots of Fruit Trees, if too strong, 10. 29. 33. 55, 56. 58. 237.

Still head Fruit Trees (see APRIL), 10. 191. 193.

Nail young Shoots, 55. 61.

Prune Pears a second time, 193.

Begin escutcheon grafting, 311.

Bud or inoculate, from the middle of this month to middle of August, 320. 500.

Dry Grass Mowings, for use, in fruit gathering time, 349.

## JULY.

Water and mulch in dry weather, 63. 217.

Scarify the stunted Fruit of Pears, 195.

Top and nail Vines, and take off the side Shoots, 222.

Bud Pear Trees, the Grafts of which have failed, 325. 500.

Thin Walnuts, and pickle them, 302.

Destroy Slugs, &c. 302.

## AUGUST.

Pick off Leaves, by degrees, from ripening Fruit, 35. 65. 73.  
Hang up Bean Stalks to catch Ear Wigs, &c. 65. 72. 261.  
397.  
Hang up Bottles for Flies and Wasps, 72. 228. 401.  
Apple Trees may yet be headed down, 140.  
Shorten fore-right Shoots of Pears, 194.  
Take Lights off from Vines in Frames, 211.  
Water Vines in hot weather, 217. 227.  
Bud or inoculate Orange Trees, 321.

## SEPTEMBER.

Bag and cover Grapes with Net or Bantine, 228, 229. 402.  
Begin to plant out well-rooted Cuttings of Gooseberries,  
251. and Currants, 258.  
Examine new-grafted Trees, 317.  
Gather Apples and Pears, by hand, when ripe, in the mid-  
dle of the day, 349. 352.

## OCTOBER.

Plant Apricot Trees, 6. Plums, 28. Peaches, 34.  
Unnail young Shoots, 10. 61. 73.  
Brush the Leaves off Trees gently, 61. 239.  
Wipe and turn Fruit that is sweating, after laying a fort-  
night, 171. 352.  
Take up Layers of Vines, 217. Currants, 258. and Rasp-  
berries, 264.  
Gather Grapes, 229.  
Prune Gooseberries, 252.

Sow Seeds of Mountain Ash, 279.

Transplant Almonds, if dry soil, 283. (See FEBRUARY.)

Sow Chesnuts, if dry weather, 292. and Walnuts, 299.

(See FEBRUARY.)

Pick up Walnuts as they drop, and pack them, 302.

Plant Fruit Trees in dry soils, 344.

Wash Trees, 389.

### NOVEMBER.

Collect leaves for Vegetable Mould, 52. 146. 219. 331. 343.  
389.

Cover Fig Trees, 237, 238.

Clear Fig Trees of the small late Fruit, 240.

Lay down Currants, 258. and begin to prune Currant  
Trees, 260.

Lay Barberries, 269.

Plant Cuttings of Mulberries, 274.

Sow Nuts, 287. and Chesnuts, 292.

### DECEMBER.

Pick and boil Shreds, 62. 398.

Ridge Borders, and sow Peas on the sides of the Ridges,  
198. 333.

Look over Chesnut Fruit, 293.

Collect Urine and Soap Suds for the Composition, 388.  
*note.*

Destroy Caterpillars, 389. Snails, 400. and Rats and  
Mice, 402.

THE END.
